DECLARATION

I hereby *declare* that the Research Thesis entitled "**STUDIES ON ANIONIC GEMINI SURFACTANTS AS CORROSION INHIBITORS ON AZ31 MAGNESIUM ALLOY**" which is being submitted to the **National Institute of Technology Karnataka Surathkal**, in partial fulfillment of the requirements for the award of the Degree of **Doctor of Philosophy** in **Chemistry** is a *bonafide report of the research work carried out by me*. The material contained in this Research Thesis has not been submitted to any University or Institution for the award of any degree.

GURURAJ ACHARYA M

Register Number: 165012CY16F02

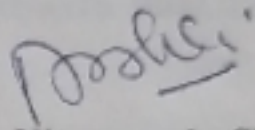

Department of Chemistry

Place: NITK - SURATHKAL

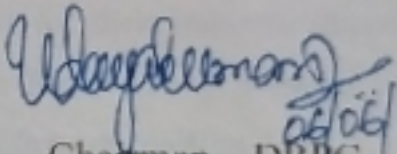

Date: 06/06/2022

CERTIFICATE

This is to *certify* that the Research Thesis entitled "STUDIES ON ANIONIC GEMINI SURFACTANTS AS CORROSION INHIBITORS ON AZ31 MAGNESIUM ALLOY" submitted by GURURAJ ACHARYA M (Register Number: 165012CY16F02) as the record of the research work carried out by him, is *accepted as the Research Thesis submission* in partial fulfillment of the requirements for the award of degree of **Doctor of Philosophy**.

Dr. A. Nityananda Shetty

Chairman - DRPC

HEAD, DEPARTMENT OF CHEMISTRY
National Institute of Technology Karnataka
Surathkal, Srikanthnagar
MANGALORE- 575 025, D.K.

ACKNOWLEDGEMENT

I will bring my deepest thank to my advisor **Dr. Adka Nityananda Shetty**, Department of Chemistry, NITK, who supported me over years to pursue a Ph.D. degree in Corrosion Lab, NITK. He would like to use all his patience, knowledge without reservations to me, to allow me to become a knowledgeable person in aqueous corrosion in these five years. I would like to also thank my RPAC members **Dr. Sib Sankar Mal** and **Dr. Shashi Bhushan Arya** who continuously gave suggestions and improvements on my research through my progress meetings.

I am grateful to **Dr. Udaya Kumar Dalimba**, Head, Department of Chemistry, National Institute of Technology Karnataka, Surathkal for providing me with the required experimental facilities of the department. I am thankful to the faculty of the Department of Chemistry, National Institute of Technology Karnataka, Surathkal, **Dr. A. C. Hegde, Dr. B. R. Bhat, Dr. D. K. Bhat, Dr. A. M. Isloor, Dr. D. R. Trivedi, Dr. Beneesh P. B, Dr. D. Chakraborty, Dr. Saikat Dutta, Dr. Vijayendra Shetti and Dr. Lakshmi** for their support.

I will bring my special thanks to **Dr. V. Aranganathan**, and **Dr. Kavyashree Keremane** for their support in my research. I also would like to thank **Dr. K. Ramesh**, Dept. of Chemistry, IITH, **Dr. Keyur Raval**, and **Mrs. Priyanka Bhat**, Dept of Chemical Engineering, for helping me in characterizations.

It is a pleasure to thank my fellow research scholars, **Dr. Prakashaiah B G** and **Dr. Sudarshan Shetty**, and all others for making my stay at NITK during research a memorable one. I would like to thank all the **non-teaching staff**, Department of Chemistry NITK, for their assistance in the laboratory.

Finally, I would like to thank my parents **Shri M. R. Acharya** and **Smt. Mohini**, my sister **Mrs. Shwetha** and all my teachers for their immense support throughout my life. Your understanding allows me to focus on my personal and professional life. I would also like to thank my professors from my college. I Thank the supreme who kept me on the right path and showered blessings all the way.

GURURAJ ACHARYA M

ABSTRACT

The magnesium alloys are considered to be the best structural materials, because of their advantageous strength to weight ratio. But, the limitation in their real field applications lies in the fact that magnesium alloys are highly susceptible for corrosion. Hence understanding the corrosion of AZ31 alloy and developing the measures to combat the same are crucial.

In the present studies, the corrosion behaviour of AZ31 alloy was investigated by electrochemical methods in sodium chloride and sodium sulphate media of different concentrations at different temperatures and followed by its inhibition studies. The corrosion rate was monitored by potentiodynamic polarization technique and electrochemical impedance spectroscopy along with SEM-EDX, and XPS. The synthesized inhibitors were subjected to theoretical studies as well. The blank corrosion studies were performed at various medium concentrations, pH and temperatures. The results revealed a trend of higher corrosion rate associated with higher medium concentration, lower pH and higher temperature.

Five different long chain anionic Gemini surfactants namely, DB, DH, DO, DC and DD were synthesized and tested as corrosion inhibitors for AZ31 alloy. The calculated activation and thermodynamic parameters have been recorded in the thesis. The inhibitors were predominantly physisorbed with partial chemisorption. The adsorption of the surfactant on the surface of AZ31 alloy obeyed Langmuir adsorption isotherm. The studied surfactants were found to function as mixed-type inhibitors. The surfactants were more efficient at lower temperatures. The efficiencies of the surfactants decreased in the order: DD>DC>DO>DH>DB and this has been accredited to the reduction of chain length. The proposed mechanism attributed the cathodic inhibition to the blockage of the reaction spots by chemisorbed acetates. The anodic inhibition resulted from the compaction of porous film by precipitated magnesium-inhibitor salts.

Keywords: AZ31 alloy, Corrosion, Inhibitor, Anionic Gemini surfactant, Impedance.

3.56	SEM image and EDX spectrum of the AZ31 magnesium alloy surface after immersion in 0.1 M NaCl in the presence of DO for 3 h at 30 °C	172
3.57	SEM image and EDX spectrum of the AZ31 magnesium alloy surface after immersion in 0.1 M Na ₂ SO ₄ in the presence of DO for 3 h at 30 °C	172
3.58	XPS survey spectra and individual spectra of elements (Mg 1s, Al 2p, C 1s, O 1s and, N 1s) of AZ31 Mg alloy immersed in 0.1 M NaCl medium in the presence of 0.001 M DO for 3 h at 30 °C	173
3.59	XPS survey spectra and individual spectra of elements (Mg 1s, Al 2p, C 1s, O 1s and, N 1s) of AZ31 Mg alloy immersed in 0.1 M Na ₂ SO ₄ medium in the presence of 0.001 M DO for 3 h at 30 °C	174

3.60	Optimized structure and the frontier molecular orbital density distribution of the DO molecule	175
3.61	Potentiodynamic polarization curves for the corrosion of AZ31 alloy in the presence of different concentrations of DC in a) 0.1 M NaCl solution and b) 0.1 M Na ₂ SO ₄ solution at 50 °C	200
3.62	Nyquist plots for the corrosion of AZ31 alloy a) in 0.1 M NaCl and b) 0.1 M Na ₂ SO ₄ in the presence of different concentrations of DC at 50 °C	201
3.63	Bode phase angle and amplitude plots for the corrosion of AZ31 alloy in 0.1 M NaCl medium in the presence of different concentrations of DC at 50 °C	202
3.64	Bode phase angle and amplitude plots for the corrosion of AZ31 alloy in 0.1 M Na ₂ SO ₄ medium in the presence of different concentrations of DC at 50 °C	202
3.65	Arrhenius plots for the corrosion of AZ31 magnesium alloy a) 0.1 M NaCl and b) 0.1 M Na ₂ SO ₄ media in the presence of different concentrations of DC	203
3.66	The plots of $\ln(v_{\text{corr}}/T)$ vs $(1/T)$ for the corrosion of AZ31 magnesium alloy in a) 0.1 M NaCl and b) 0.1 M Na ₂ SO ₄ in the presence of different concentrations of DC	203
3.67	Langmuir adsorption isotherm for the adsorption of DC on AZ31 magnesium alloy in a) 0.1 M NaCl medium and b) 0.1 M Na ₂ SO ₄ medium	205
3.68	SEM image and EDX spectrum of the AZ31 magnesium alloy surface immersed in 0.1 M NaCl in the presence of DC for 3 h at 30 °C	206
3.69	SEM image and EDX spectrum of the AZ31 magnesium alloy surface immersed in 0.1 M Na ₂ SO ₄ in the presence of DC for 3 h at 30 °C	206
3.70	XPS survey spectra and individual spectra of elements (Mg 2s, Al 2p, C 1s, O 1s and, N 1s) of AZ31 Mg alloy immersed in 0.1 M NaCl medium in the presence of 0.001 M DC for 3 h at 30 °C	207
3.71	XPS survey spectra and individual spectra of elements (Mg 2s, Al 2p, C 1s, O 1s and, N 1s) of AZ31 Mg alloy immersed in 0.1 M Na ₂ SO ₄ medium in the presence of 0.001 M DC for 3 h at 30 °C	207
3.72	Optimized structure and the frontier molecular orbital density distribution of the DC molecule	209
3.73	Potentiodynamic polarization curves for the corrosion of AZ31 alloy in the presence of different concentrations of DD in a) 0.1 M NaCl solution and b) 0.1 M Na ₂ SO ₄ solution at 50 °C	234
3.74	Nyquist plots for the corrosion of AZ31 alloy in the presence of different concentrations of DD a) in 0.1 M NaCl and b) 0.1 M Na ₂ SO ₄ at 50 °C	235

3.75	Bode phase angle and amplitude plots for the corrosion of AZ31 alloy in 0.1 M NaCl medium containing different concentrations of DD at 50 °C	236
3.76	Bode phase angle and amplitude plots for the corrosion of AZ31 alloy in 0.1 M Na ₂ SO ₄ medium containing different concentrations of DD at 50 °C	236
3.77	Arrhenius plots for the corrosion of AZ31 magnesium alloy for in a) 0.1 M NaCl and b) 0.1 M Na ₂ SO ₄ media in the presence of different concentrations of DD	237
3.78	The plots of $\ln(v_{\text{corr}}/T)$ vs $(1/T)$ for the corrosion of AZ31 magnesium alloy for in a) 0.1 M NaCl and b) 0.1 M Na ₂ SO ₄ media in the presence of different concentrations of DD	237
3.79	Langmuir adsorption isotherm for the adsorption of DD compound on AZ31 magnesium alloy in a) 0.1 M NaCl medium and b) 0.1 M Na ₂ SO ₄ medium	238
3.80	SEM image and EDX spectrum of the AZ31 magnesium alloy surface immersed in 0.1 M NaCl in the presence of DD for 3 h at 30 °C	239
3.81	SEM image and EDX spectrum of the AZ31 magnesium alloy surface immersed in 0.1 M Na ₂ SO ₄ in the presence of DD for 3 h at 30 °C	239
3.82	XPS survey spectra and individual spectrum of elements (Mg 1s, Al 2p, C 1s, O 1s and, N 1s) of AZ31 Mg alloy immersed in 0.1 M NaCl medium in the presence of 0.0002 M DD for 3 h at 30 °C	240
3.83	XPS survey spectra and individual spectrum of elements (Mg 1s, Al 2p, C 1s, O 1s and, N 1s) of AZ31 Mg alloy immersed in 0.1 M Na ₂ SO ₄ medium in the presence of 0.0002 M DD for 3 h at 30 °C	240
3.84	Optimized structure and the frontier molecular orbital density distribution of the DD molecule	242

LIST OF TABLES

Table No.	Contents	Page No.
1.1	Physical and mechanical properties of AZ31 alloy	32
1.2	Eminent corrosion inhibitors for magnesium and magnesium alloys	34
1.3	Strategies for corrosion control of AZ31 alloy	36
1.4	Surfactants as corrosion inhibitors	40
2.1	Composition of specimen (in terms of weight%)	45
2.2	The valence, weight fraction and atomic weight of major elements present in AZ31 alloy	55
2.3	List of adsorption isotherms	57
3.1	Electrochemical polarization parameters for the corrosion of AZ31 alloy in NaCl media at different temperatures	75
3.2	Electrochemical polarization parameters for the corrosion of AZ31 alloy in Na ₂ SO ₄ media at different temperatures	76
3.3	Electrochemical impedance parameters for the corrosion of AZ31 alloy in NaCl media at different temperatures	77
3.4	Electrochemical impedance parameters for the corrosion of AZ31 alloy in Na ₂ SO ₄ media at different temperatures	78
3.5	Activation parameters for the corrosion of AZ31 alloy in different concentrations of NaCl	79
3.6	Activation parameters for the corrosion of AZ31 alloy in different concentrations of Na ₂ SO ₄	79
3.7	Electrochemical polarization parameters for the corrosion of AZ31 alloy in NaCl medium of different pH and concentrations at 30 °C	86
3.8	Electrochemical polarization parameters for the corrosion of AZ31 alloy in Na ₂ SO ₄ medium of different pH and concentrations at 30 °C	87
3.9	Electrochemical impedance parameters for the corrosion of AZ31 alloy in NaCl medium of different pH and concentrations at 30 °C	88
3.10	Electrochemical impedance parameters for the corrosion of AZ31 alloy in Na ₂ SO ₄ medium of different pH and concentrations at 30 °C	89
3.11	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.05 M NaCl solution in the presence of DB at different temperatures	106
3.12	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.10 M NaCl solution in the presence of DB at different temperatures	107
3.13	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.15 M NaCl solution in the presence of DB at different temperatures	108

3.14	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.20 M NaCl solution in the presence of DB at different temperatures	109
3.15	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.25 M NaCl solution in the presence of DB at different temperatures	110
3.16	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.05 M Na ₂ SO ₄ solution in the presence of DB at different temperatures	111
3.17	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.10 M Na ₂ SO ₄ solution in the presence of DB at different temperatures	112
3.18	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.15 M Na ₂ SO ₄ solution in the presence of DB at different temperatures	113
3.19	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.20 M Na ₂ SO ₄ solution in the presence of DB at different temperatures	114
3.20	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.25 M Na ₂ SO ₄ solution in the presence of DB at different temperatures	115
3.21	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.05 M NaCl solution in the presence of DB at different temperatures	116
3.22	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.10 M NaCl solution in the presence of DB at different temperatures	117
3.23	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.15 M NaCl solution in the presence of DB at different temperatures	118
3.24	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.20 M NaCl solution in the presence of DB at different temperatures	119
3.25	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.25 M NaCl solution in the presence of DB at different temperatures	120
3.26	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.05 M Na ₂ SO ₄ solution in the presence of DB at different temperatures	121
3.27	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.10 M Na ₂ SO ₄ solution in the presence of DB at different temperatures	122
3.28	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.15 M Na ₂ SO ₄ solution in the presence of DB at different temperatures	123

3.29	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.20 M Na ₂ SO ₄ solution in the presence of DB at different temperatures	124
3.30	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.25 M Na ₂ SO ₄ solution in the presence of DB at different temperatures	125
3.31	Activation parameters for the corrosion of AZ31 alloy in NaCl solutions containing different concentrations of DB inhibitor	126
3.32	Activation parameters for the corrosion of AZ31 alloy in Na ₂ SO ₄ solutions containing different concentrations of DB inhibitor	127
3.33	Thermodynamic parameters for the adsorption of DB on AZ31 alloy in NaCl solution	128
3.34	Thermodynamic parameters for the adsorption of DB on AZ31 alloy in Na ₂ SO ₄ solution	129
3.35	Calculated DFT parameters for DB inhibitor	129
3.36	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.05 M NaCl solution in the presence of DH at different temperatures	142
3.37	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.10 M NaCl solution in the presence of DH at different temperatures	143
3.38	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.15 M NaCl solution in the presence of DH at different temperatures	144
3.39	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.20 M NaCl solution in the presence of DH at different temperatures	145
3.40	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.25 M NaCl solution in the presence of DH at different temperatures	146
3.41	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.05 M Na ₂ SO ₄ solution in the presence of DH at different temperatures	147
3.42	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.10 M Na ₂ SO ₄ solution in the presence of DH at different temperatures	148
3.43	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.15 M Na ₂ SO ₄ solution in the presence of DH at different temperatures	149
3.44	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.20 M Na ₂ SO ₄ solution in the presence of DH at different temperatures	150
3.45	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.25 M Na ₂ SO ₄ solution in the presence of DH at different temperatures	151

3.46	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.05 M NaCl solution in the presence of DH at different temperatures	152
3.47	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.10 M NaCl solution in the presence of DH at different temperatures	153
3.48	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.15 M NaCl solution in the presence of DH at different temperatures	154
3.49	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.20 M NaCl solution in the presence of DH at different temperatures	155
3.50	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.25 M NaCl solution in the presence of DH at different temperatures	156
3.51	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.05 M Na ₂ SO ₄ solution in the presence of DH at different temperatures	157
3.52	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.10 M Na ₂ SO ₄ solution in the presence of DH at different temperatures	158
3.53	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.15 M Na ₂ SO ₄ solution in the presence of DH at different temperatures	159
3.54	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.20 M Na ₂ SO ₄ solution in the presence of DH at different temperatures	160
3.55	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.25 M Na ₂ SO ₄ solution in the presence of DH at different temperatures	161
3.56	Activation parameters for the corrosion of AZ31 alloy in NaCl solutions containing different concentrations of DH inhibitor	162
3.57	Activation parameters for the corrosion of AZ31 alloy in Na ₂ SO ₄ solutions containing different concentrations of DH inhibitor	163
3.58	Thermodynamic parameters for the adsorption of DH on AZ31 alloy in NaCl solution	164
3.59	Thermodynamic parameters for the adsorption of DH on AZ31 alloy in Na ₂ SO ₄ solution	165
3.60	Calculated DFT parameters for DH inhibitor	165
3.61	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.05 M NaCl solution in the presence of DO at different temperatures	176
3.62	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.10 M NaCl solution in the presence of DO at different temperatures	177

3.63	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.15 M NaCl solution in the presence of DO at different temperatures	178
3.64	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.20 M NaCl solution in the presence of DO at different temperatures	179
3.65	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.25 M NaCl solution in the presence of DO at different temperatures	180
3.66	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.05 M Na ₂ SO ₄ solution in the presence of DO at different temperatures	181
3.67	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.10 M Na ₂ SO ₄ solution in the presence of DO at different temperatures	182
3.68	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.15 M Na ₂ SO ₄ solution in the presence of DO at different temperatures	183
3.69	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.20 M Na ₂ SO ₄ solution in the presence of DO at different temperatures	184
3.70	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.25 M Na ₂ SO ₄ solution in the presence of DO at different temperatures	185
3.71	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.05 M NaCl solution in the presence of DO at different temperatures	186
3.72	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.10 M NaCl solution in the presence of DO at different temperatures	187
3.73	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.15 M NaCl solution in the presence of DO at different temperatures	188
3.74	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.20 M NaCl solution in the presence of DO at different temperatures	189
3.75	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.25 M NaCl solution in the presence of DO at different temperatures	190
3.76	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.05 M Na ₂ SO ₄ solution in the presence of DO at different temperatures	191
3.77	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.10 M Na ₂ SO ₄ solution in the presence of DO at different temperatures	192

3.78	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.15 M Na ₂ SO ₄ solution in the presence of DO at different temperatures	193
3.79	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.20 M Na ₂ SO ₄ solution in the presence of DO at different temperatures	194
3.80	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.25 M Na ₂ SO ₄ solution in the presence of DO at different temperatures	195
3.81	Activation parameters for the corrosion of AZ31 alloy in NaCl solutions containing different concentrations of DO inhibitor	196
3.82	Activation parameters for the corrosion of AZ31 alloy in Na ₂ SO ₄ solutions containing different concentrations of DO inhibitor	197
3.83	Thermodynamic parameters for the adsorption of DO on AZ31 alloy in NaCl solution	198
3.84	Thermodynamic parameters for the adsorption of DO on AZ31 alloy in Na ₂ SO ₄ solution	199
3.85	Calculated DFT parameters for DO inhibitor	199
3.86	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.05 M NaCl solution in the presence of DC at different temperatures	210
3.87	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.10 M NaCl solution in the presence of DC at different temperatures	211
3.88	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.15 M NaCl solution in the presence of DC at different temperatures	212
3.89	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.20 M NaCl solution in the presence of DC at different temperatures	213
3.90	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.25 M NaCl solution in the presence of DC at different temperatures	214
3.91	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.05 M Na ₂ SO ₄ solution in the presence of DC at different temperatures	215
3.92	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.10 M Na ₂ SO ₄ solution in the presence of DC at different temperatures	216
3.93	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.15 M Na ₂ SO ₄ solution in the presence of DC at different temperatures	217
3.94	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.20 M Na ₂ SO ₄ solution in the presence of DC at different temperatures	218

3.95	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.25 M Na ₂ SO ₄ solution in the presence of DC at different temperatures	219
3.96	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.05 M NaCl solution in the presence of DC at different temperatures	220
3.97	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.10 M NaCl solution in the presence of DC at different temperatures	221
3.98	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.15 M NaCl solution in the presence of DC at different temperatures	222
3.99	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.20 M NaCl solution in the presence of DC at different temperatures	223
3.100	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.25 M NaCl solution in the presence of DC at different temperatures	224
3.101	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.05 M Na ₂ SO ₄ solution in the presence of DC at different temperatures	225
3.102	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.10 M Na ₂ SO ₄ solution in the presence of DC at different temperatures	226
3.103	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.15 M Na ₂ SO ₄ solution in the presence of DC at different temperatures	227
3.104	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.20 M Na ₂ SO ₄ solution in the presence of DC at different temperatures	228
3.105	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.25 M Na ₂ SO ₄ solution in the presence of DC at different temperatures	229
3.106	Activation parameters for the corrosion of AZ31 alloy in NaCl solutions containing different concentrations of DC inhibitor	230
3.107	Activation parameters for the corrosion of AZ31 alloy in Na ₂ SO ₄ solutions containing different concentrations of DC inhibitor	231
3.108	Thermodynamic parameters for the adsorption of DC on AZ31 alloy in NaCl solution	232
3.109	Thermodynamic parameters for the adsorption of DC on AZ31 alloy in Na ₂ SO ₄ solution	233
3.110	Calculated DFT parameters for DC inhibitor	233
3.111	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.05 M NaCl solution in the presence of DD at different temperatures	245

3.112	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.10 M NaCl solution in the presence of DD at different temperatures	246
3.113	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.15 M NaCl solution in the presence of DD at different temperatures	247
3.114	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.20 M NaCl solution in the presence of DD at different temperatures	248
3.115	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.25 M NaCl solution in the presence of DD at different temperatures	249
3.116	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.05 M Na ₂ SO ₄ solution in the presence of DD at different temperatures	250
3.117	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.10 M Na ₂ SO ₄ solution in the presence of DD at different temperatures	251
3.118	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.15 M Na ₂ SO ₄ solution in the presence of DD at different temperatures	252
3.119	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.20 M Na ₂ SO ₄ solution in the presence of DD at different temperatures	253
3.120	Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.25 M Na ₂ SO ₄ solution in the presence of DD at different temperatures	254
3.121	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.05 M NaCl solution in the presence of DD at different temperatures	255
3.122	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.10 M NaCl solution in the presence of DD at different temperatures	256
3.123	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.15 M NaCl solution in the presence of DD at different temperatures	257
3.124	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.20 M NaCl solution in the presence of DD at different temperatures	258
3.125	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.25 M NaCl solution in the presence of DD at different temperatures	259
3.126	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.05 M Na ₂ SO ₄ solution in the presence of DD at different temperatures	260

3.127	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.10 M Na ₂ SO ₄ solution in the presence of DD at different temperatures	261
3.128	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.15 M Na ₂ SO ₄ solution in the presence of DD at different temperatures	262
3.129	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.20 M Na ₂ SO ₄ solution in the presence of DD at different temperatures	263
3.130	Electrochemical impedance parameters for the corrosion of AZ31 alloy in 0.25 M Na ₂ SO ₄ solution in the presence of DD at different temperatures	264
3.131	Activation parameters for the corrosion of AZ31 alloy in NaCl solutions containing different concentrations of DD inhibitor	265
3.132	Activation parameters for the corrosion of AZ31 alloy in Na ₂ SO ₄ solutions containing different concentrations of DD inhibitor	266
3.133	Thermodynamic parameters for the adsorption of DD on AZ31 alloy in NaCl solution	267
3.134	Thermodynamic parameters for the adsorption of DD on AZ31 alloy in Na ₂ SO ₄ solution	268
3.135	Calculated DFT parameters for DD inhibitor	268

NOMENCLATURE

Abbreviations	Nomenclature
CPE	Constant phase element
DC	Direct Current
EDTA	Ethylenediamine tetraacetic acid
EDX	Electron dispersive x-ray analysis
EIS	Electrochemical impedance spectroscopy
EW	Equivalent weight of the corroding material
Fig	Figure
HF	High frequency
LF	Low frequency
MF	Medium frequency
OCP	Open circuit potential
SCC	Stress Corrosion Cracking
SCE	Saturated calomel electrode
SEM	Scanning electron microscopy
DB	Sodium 2,2'-(5,14-dibutyl-6,13-dioxo-5,8,11,14-tetrazaoctadecane-8,11-diyl)diacetate
DH	Sodium 2,2'-(7,16-dihexyl-8,15-dioxo-7,10,13,16-tetraazadocosane-10,13-diyl)diacetate
DO	Sodium 2,2'-(9,18-dioctyl-10,17-dioxo-9,12,15,18-tetraazahexacosane-12,15-diyl)diacetate
DC	Sodium 2,2'-(11,20-didecyl-12,19-dioxo-11,14,17,20-tetraazatriacontane-14,17-diyl)diacetate
DD	Sodium 2,2'-(13,22-didodecyl-14,21-dioxo-11,14,17,20-tetraazatetatriacontane-16,19-diyl)diacetate
XPS	X-ray photoelectron spectroscopy

LIST OF SYMBOLS

Symbol	Definition
T	Absolute temperature
E_a	Activation energy
ω	Angular frequency
N	Avagadro's number
W_i	Atomic weight of the i^{th} element in the alloy
β_c	Cathodic Tafel slope
R_{ct}	Charge transfer resistance
C_{inh}	Concentration of the inhibitor
Y_0	Constant phase element constant
B	Constant
K	Constant
i_{corr}	Corrosion current density
$i_{corr(inh)}$	Corrosion current density in the presence of inhibitor
E_{corr}	Corrosion potential
v_{corr}	Corrosion rate
ρ	Density of the corroding material
C_{dl}	Double layer capacitance
E_0	Electrode potential for zero current at equilibrium
$\Delta H^{\#}$	Enthalpy of activation
$\Delta S^{\#}$	Entropy of activation
i_0	Exchange current density
R_f	Film resistance
F	Faraday constant
ΔG	Free energy change
ω_{max}	Frequency at which imaginary part of the impedance has a maximum
R	Gas constant
Z''	Imaginary part impedance
Z_{mod}	Impedance modulus
η	Inhibition efficiency
R^2	Linear regression coefficient
ε	Local dielectric constant
f_i	Mass fraction of the i^{th} element in the alloy
n	Number of electrons in a reaction
χ	Number of water molecules replaced per molecule of adsorbed inhibitor
R_{hf}	Overall resistance associated with higher frequency capacitive loop

$R_{hf(b)}$	Overall resistance associated with higher frequency capacitive loop in the absence of the inhibitor
$R_{hf(inh)}$	Overall resistance associated with higher frequency capacitive loop in the presence of the inhibitor
θ_{max}	Phase maximum
φ	Phase shift
h	Plank's constant
R_p	Polarization resistance
Z'	Real part of impedance
R_{dif}	Resistance associated with electrolyte diffusion
E^0	Rest potential
ΔH^0_{ads}	Standard enthalpy of adsorption
ΔS^0_{ads}	Standard entropy of adsorption
R_s	Solution resistance
θ	Surface coverage
d	Thickness of the film
t	Time
n_i	Valence of the i^{th} element of the alloy

CHAPTER-1
INTRODUCTION

CHAPTER 1

INTRODUCTION

Corrosion is the disastrous attack on a metal by its surroundings through a chemical or electrochemical reaction. About one-quarter of the world's annual steel production is destroyed by corrosion. On certain occasions, the chemical attack goes with physical weakening, as depicted by the accompanying terms: erosion-corrosion, corrosive wear, or fretting corrosion. Few insist that the statement must be restricted to metals, but many corrosion engineers had considered both metals and non-metals for the solution of a given problem. Non-metals are not considered for this definition of corrosion. Plastics may expand or crack, wood may split or decay, stones may erode, and Portland concrete may spoil away, yet the term corrosion, here, is confined to chemical substances attacking metals. For example, iron railroad tracks show little less rusting over the years than 18-8 stainless steel that is badly attacked in hours by polythionic acid (Sastri 1998).

Although many other metals form their oxides when corrosion occurs, corrosion of iron or iron-based alloys, with their corrosion products, largely of hydrous ferric oxides is called "rusting".

The three main bases for the significance of corrosion are economics, safety, and conservation. In order to suppress the impact of corrosion, scientists aim to reduce material losses, as well as the go with economic losses, that result from the corrosion of metallic materials and installations such as pipings, tanks, metal components of machines, ships, bridges, marine structures, and so on.

Indirect losses are highly laborious to assess, yet, the direct losses such as replacing corroded structures and machinery or their components, such as condenser tubes, mufflers, pipelines, and metal roofing, including the necessary labor cost amount to a large amount of money. Examples of indirect losses are shutdown, loss of product, loss of efficiency, and contamination of products. Another important concern is the world's supply of metal resources. The rapid industrializations of many countries indicate that the competition for the price of metal resources will increase. Due to corrosion, useful

metal properties such as malleability, ductility, electrical conductivity, and also surface appearance are lost (Fontana 2005).

1.1 DAMAGE DUE TO CORROSION

A few of the major effects of corrosion are listed below. However, corrosion is desirable in some cases. For example, aircraft and other machines use chemical milling and chemical machining. Excess metal is dissolved for an uncovered surface that is been exposed to acids. This process is economical and is used when the conventional method cannot be reached to some parts of the machine.

- **Appearance:** The automobile vehicles are painted for better appearance and rust-free surfaces. Machines corrode and badly get rusted when equipments are kept in a plant over the years, and that would showcase poor impression on the observer.
- **Maintenance and operating costs:** Substantial savings can be made in many types of industrial plants through the use of corrosion-resistant materials of construction. One example is the waste acid recovery plant operated for several months was stopped until a serious corrosion problem was solved. The application of cathodic protection can reduce corrosion rates in existing underground pipelines.
- **Plant shutdowns:** Frequently plants are shut down or part of a process in an industry is stopped because of unexpected corrosion failures. Sometimes these shutdowns are caused by corrosion that involves no change in process conditions, but occasionally they are caused by changes in operating procedures erroneously regarded as incapable of increasing the severity of the corrosive conditions. For example, to increase the production of a chemical compound, a company decided to lower the temperature of the cooling medium in a heat-exchanger system and the time required per batch decreased. But, induced higher stresses in the metal. Stress corrosion cracking (SCC) of the vessels occurred quickly, and the plant was shut down with production delayed for some time.

Corrosion monitoring of an industrial plant process helps prevent unexpected plant shutdown.

- **Contamination of product:** In many case studies, the price of the product is directly related to its purity and quality. Free from contamination is an important factor in the manufacture and handling of transparent plastics, dyes, foods, drugs, and semiconductors. One of the examples in this case is manufacture and transporting of concentrated hydrogen peroxide or hydrazine in which case, a very small amount of corrosion, which introduces certain metal ions into the solution, may cause catalytic decomposition of the product.
- **Loss of valuable products:** No particular concern is attached if slight leakage of acid to the drainage system, but the loss of material in huge amount requires immediate corrective action. Slight losses of uranium compounds or solutions are hazardous and can be very costly. In such cases, utilization of more expensive designs and better materials of construction are well warranted.
- **Effects on safety and reliability:** The handling of toxic materials such as HF, radioactive substances, and chemicals at high temperatures and pressures demands the use of construction materials that minimize corrosion failures. Stress corrosion of a metal wall separating the fuel and oxidizer in a missile could cause premature mixing, which could result in a loss of a huge amount of money.

Corrosion plays a vital part in medical metals used by orthopedics, such as hip joints, screws, plates, and heart valves. Reliability is, of course, of paramount importance here (Fontana 2005) (Uhlig 2011).

1.2 ELECTROCHEMICAL THEORY OF CORROSION

As per this hypothesis, corrosion of metals take place due to the formation of anodic and cathodic regions on the same metal surface or when two different metals are in contact with one another in the presence of a conducting medium. At the anodic region, the metal undergoes oxidation, forming the oxidized product and liberating electrons. At the cathodic area, a reduction reaction takes place. The constituents of the corrosion medium undergo reduction at the cathode. The oxidation reaction at the anodic region and the reduction reaction at the cathodic region must continue simultaneously at the same rate to maintain electroneutrality. The electrons generated by the anodic reactions migrate to the cathodic region,

constituting the corrosion current and the electrons are consumed in the cathodic process. The metal ions formed at the anode and the anions formed at the cathode diffuse towards each other through the conducting medium and form a corrosion product somewhere in between the anode and the cathode (Fontana 2005).

Corrosion reactions

At the anodic region: The metal that gets converted into ions with the liberation of electrons.

At the cathodic region: Depending on the nature of the corrosion medium/environment the following reactions may take place at the cathode.

1.3 CLASSIFICATION OF CORROSION

The corrosion process can be classified based on various perspectives. Based on the temperature conditions at which the corrosion takes place, it is distinguished as low-temperature and high-temperature corrosion. Another classification is a direct chemical attack and electrochemical corrosion. They are also known as dry corrosion and wet corrosion, respectively, as they take place in the absence and presence of moisture or conducting medium (Fontana 2005).

1.3.1 Forms of corrosion

Based on the appearance of the corroded surface by visual examination, the different types of corrosion have been classified into eight types. The eight types are as follows (Fontana 2005):

1.3.1.1 Uniform attack

Uniform corrosion is a loss of material distributed uniformly over the entire surface exposed to the corrosive environment. Metals in contact with strong acids

are sometimes subjected to uniform corrosion. The material becomes thinner and breaks eventually. For example, a sheet-iron roof will show essentially the same degree of rusting over its entire outside surface. It is also called general overall corrosion, represents the greatest destruction of metal on a large basis.

1.3.1.2 Crevice corrosion

It is caused by a difference in oxygen availability between two sites on a passive metal that leads to the formation of an electrochemical cell. A selective attack within cracks and at other sites of poor oxygen access is frequently observed.

The most common is oxygen differential aeration corrosion. This occurs when the oxygen supply is less in crevice than on the surface layer. In lower oxygen levels, it forms an anode. The metal surface that is exposed to air moisture forms a cathode.

1.3.1.3 Filliform corrosion

It is a special type of crevice corrosion, occurring under protective films, and for this reason, it is often referred to as filliform corrosion. An example of this type of corrosion is the attack of enameled or lacquered surfaces of food and beverage cans that have been exposed to the atmosphere. Filliform corrosion is an unusual type of attack, since it does not weaken or destroy metallic components but only affects surface appearance.

1.3.1.4 Pitting corrosion

It is observed on passive metals in presence of certain anions (in particular chloride) when the potential exceeds a critical value. This process typically produces cavities with diameters on the order of several tens of micrometers. Pitting is a form of extremely localized attack that results in holes in the metal. These holes may be small or large in diameter, but in most cases, they are relatively small. Pits are sometimes isolated or so close together that they look like a rough surface. Pitting is particularly vicious because it is a localized and intense form of corrosion, and failures often occur with extreme suddenness. For example, iron buried in the soil corrodes with the formation of shallow pits, whereas stainless steels immersed in seawater characteristically corrode with the formation of deep pits.

1.3.1.5 Intergranular corrosion

Intergranular corrosion is a selective attack of grain boundaries. Often, it is related to thermal treatments that lead to preferred precipitation of phases at grain

boundaries. The alloy disintegrates (grain fall out) and/or loses its strength. It can be caused by impurities at the grain boundaries, enrichment of one of the alloying elements, or depletion of one of these elements in the grain-boundary area.

1.3.1.6 Erosion corrosion

It is the result of an electrochemical reaction combined with a material loss by mechanical wear due to the impingement of solids or a fluid. The increase in the rate of depletion or attack on material because of relative movement between a corrosive fluid and the metal surface is called erosion corrosion. Usually, this movement is very fast, and abrasion is involved. Metal is removed from the surface as dissolved ions. Erosion corrosion is characterized in appearance by grooves, gullies, waves, and valleys and usually exhibits a directional pattern.

1.3.1.7 Stress corrosion

It results from the combined action of corrosion and of mechanical stress. It manifests itself by crack formation at stress levels well below the ultimate tensile strength of a material. During stress-corrosion cracking, the metal or alloy is virtually unattacked over most of its surface, while fine cracks progress through it. This cracking phenomenon can have serious consequences since it can occur at stresses within the range of typical design stress.

1.3.1.8 Hydrogen damage

Hydrogen can cause several corrosion problems. Hydrogen embrittlement is a problem with high-strength steels, titanium, and some other metals. Hydrogen blistering can occur when hydrogen enters steel as a result of the reduction reaction on a metal cathode. Single-atom nascent hydrogen atoms then diffuse through the metal until they meet with another atom, usually at inclusions or defects in the metal. The resultant diatomic hydrogen molecules are then too big to migrate and become trapped.

Hydrogen blistering is not restricted to installations containing high-pressure hydrogen gas. A corrosion reaction involving the reduction of protons, for example during pickling of steel, can also be responsible for this type of damage (Sastri 1998).

1.4 FACTORS INFLUENCING CORROSION RATE

Numerous factors impact the rate of corrosion. These factors are classified into two main groups, as related to the nature of the metal, and the nature of the environment or corrosion medium (Gadag and Shetty 2010).

1.4.1 Nature of the metal

The nature of a metal or an alloy significantly influences the corrosion rate, irrespective of the corrosion medium. Some of the properties of the metal, which potentially influence the mechanism as well as the corrosion rate are explained below.

1.4.1.1 Purity of the metal

A pure metal is safer against corrosion than its alloy which is a commercial counterpart. Yet, the metals of most elevated virtues are costly and precisely weak, confining their utilization. During the production and when they are subjected to different metallurgical processes to enhance their properties, they develop inhomogeneities in them. These may include the formation of inclusions, different crystallographic orientations, grain and grain boundaries, different phases, scratches, etc. These changes will initiate and stimulate the corrosion.

1.4.1.2 Electrode potential of metal

The standard electrode potential is the benchmark to decide the tendency of a metal to undergo corrosion. The metal with lower electrode potential is more susceptible for corrosion than a noble metal with a higher electrode potential. Thus, metals like magnesium and zinc with lower electrode potential are less resistant to corrosion than noble metals like platinum and gold with high electrode potential. But there are exceptions to this pattern as seen with metals like aluminium, because of surface passivation. The coupling of two metals with a small difference in their electrode potentials will minimize the risk of corrosion.

1.4.1.3 Hydrogen overvoltage on the metal surface

The metal with lower hydrogen overvoltage on its surface is more susceptible to corrosion when the cathodic reaction which is an evolution of hydrogen gas. Lower

hydrogen overvoltage facilitates the easy release of hydrogen gas. Consequently, cathodic reaction becomes faster, which, in turn makes the anodic reaction faster. The higher the hydrogen overvoltage lesser is the corrosion rate.

1.4.1.4 Relative areas of the anodic and cathodic region

The rate of corrosion is impacted by the relative areas of the cathodic and anodic regions. If a small anodic region is in contact with a large cathodic region, then the electrons are consumed at a faster rate at the cathodic region, forcing the anodic dissolution of the metal to proceed with the maximum optimum rate and thus increasing the corrosion rate.

1.4.1.5 Nature of the corrosion product

The nature of the corrosion product formed on the surface decides whether the rate of corrosion is high or low. The corrosion product formed like metal oxide may act as a protective film. If the oxide layer, which forms on the surface, is highly insoluble and non-porous in nature with low ionic and electronic conductivity, then that type of products layer effectively prevents further corrosion, by acting as a barrier between the metal surface and corrosion medium. On the other hand, if the corrosion product is unstable, porous, and soluble, it increases corrosion.

1.4.2 Environmental factors

The nature of the corrosive medium has an equivalent effect on the rate of metal corrosion as that of the nature of metal. Some of the environmental factors which have a significant effect on the corrosion rate are explained below.

1.4.2.1 Temperature

Corrosion rate increases with an increase in the temperature of the corrosion medium. This is because of the increase in the conductance of the medium with the increase in temperature.

1.4.2.2 pH of medium studies

The pH of the medium influences the rate of cathodic reaction by affecting the availability of H^+ ions for the cathodic reactions. Therefore, a decrease in pH increases

the rate of corrosion. Amphoteric metals such as aluminium, lead, and zinc are the exceptions, which undergo significant corrosion at higher pH values of the medium also.

1.4.2.3 Humidity

It is observed that corrosion rate increases with an increase in humidity of the environment. The presence of moisture provides conducting medium for the formation of a galvanic cell, thus facilitating corrosion of metal.

1.4.2.4 Presence of impurities

The presence of certain impurities in the environment increases the corrosiveness of the medium. For instance, pollutants like SO_2 combine with the dampness in the condition, forming sulphuric acid. Increased acidity brings about a rise in the corrosion rate of the metals.

1.4.2.5 Electrical conductivity of medium

Corrosion rate increases with the increase in the conductivity of the medium. Higher the conductivity quicker will be the movement of ions between the cathodic and anodic regions, increasing the rate of corrosion. It is because of the higher electrical conductivity that ocean water is more corrosive than freshwater.

1.4.2.6 Presence of oxygen and oxidizers

It is seen that the effect of oxidizer additions or the presence of oxygen on corrosion rate depends on both the medium and the metal involved in the system. The corrosion rate may be increased by the addition of oxidizers, oxidizers may not affect the corrosion rate, or a very complex behavior may be observed.

Knowing the basic characteristics of a metal/metal alloy and the medium to which it is exposed, it is possible to predict in many instances the effect of oxidizer additions.

1.4.2.7 Effect of velocity

The effects of velocity on corrosion rate are, like the effects of oxidizer additions, complex and depend on the characteristics of the metal and the environment to which it is exposed. For corrosion processes that are controlled by activation polarization, agitation and velocity do not affect the corrosion rate. If the corrosion process is under cathodic diffusion control, then agitation increases the corrosion rate.

1.4.2.8 Effect of Concentration of medium

Many materials that exhibit passivity effects are only negligibly affected by wide changes in corrosive concentration. Similarly, few other materials show the same behavior except that at very high corrosive concentrations, the corrosion rate increases rapidly.

1.4.2.9 Polarization of anodic and cathodic regions

Polarization of cathode or anode decreases the rate of corrosion. If anodic polarization takes place, the tendency of the metal to undergo oxidation decreases, decreasing the rate of corrosion. Anodic polarization results from the accumulation of metal ions formed at the anode and/or due to the passivation of the anode surface. Cathodic polarization is either due to the activation polarization or due to the concentration polarization resulting from the decelerated diffusion of cathodic reactants.

1.5 THERMODYNAMICS OF CORROSION

Thermodynamics, the science of energy change, has been widely applied to corrosion studies for many years. Below, the principles applicable to corrosion phenomena and their limitations are reviewed (Sastri 1998).

1.5.1 Concept of free energy

The free-energy change accompanying an electrochemical reaction can be calculated by the following equation:

$$\Delta G = -nFE \quad (1.7)$$

where ΔG is the free-energy change, n is the number of electrons involved in the reaction, F is the Faraday constant, and E is the cell potential.

Therefore, for a given corrosion reaction to take place, the cell potential should be positive. The cell potential is taken as the difference between the potentials of two half-cell reactions. Assuming hydrogen evolution as a reaction at the cathode, the following relations are obtained.

$$E_{cell} = E\left(\frac{H^+}{H_2}\right) - E(M^{n+}/M) \quad (1.8)$$

It follows that metals with negative standard electrode potential, electrochemical cell potential will be positive and thus the process of corrosion occurs ($\Delta G = -ve$). Corrosion will not occur unless the reaction of metal oxidation (anodic metal dissolution) is spontaneous.

1.5.2 Application of thermodynamics to corrosion

The applications of thermodynamics to corrosion phenomena have been further generalized using potential-pH plots. These are frequently called Pourbaix diagrams, after M. Pourbaix who first suggested their use (Pourbaix 1974).

The main uses of these diagrams are (1) predicting the spontaneous direction of reactions, (2) estimating the composition of corrosion products, and (3) predicting the environmental changes that will prevent or reduce corrosive attacks.

The Pourbaix diagram for the pure magnesium-water system at 25 °C is shown in Fig. 1.1 (Pourbaix 1974). As shown by the diagram, magnesium is susceptible to corrosion under potentials more positive than -2.37 V (E° of magnesium) and pH below 10.5. A narrow corrosion immune region exists at potentials more negative than the standard electrode potential of magnesium. The passive region exists at highly alkaline conditions (pH > 10.5), which favor the formation of magnesium hydroxide precipitation.

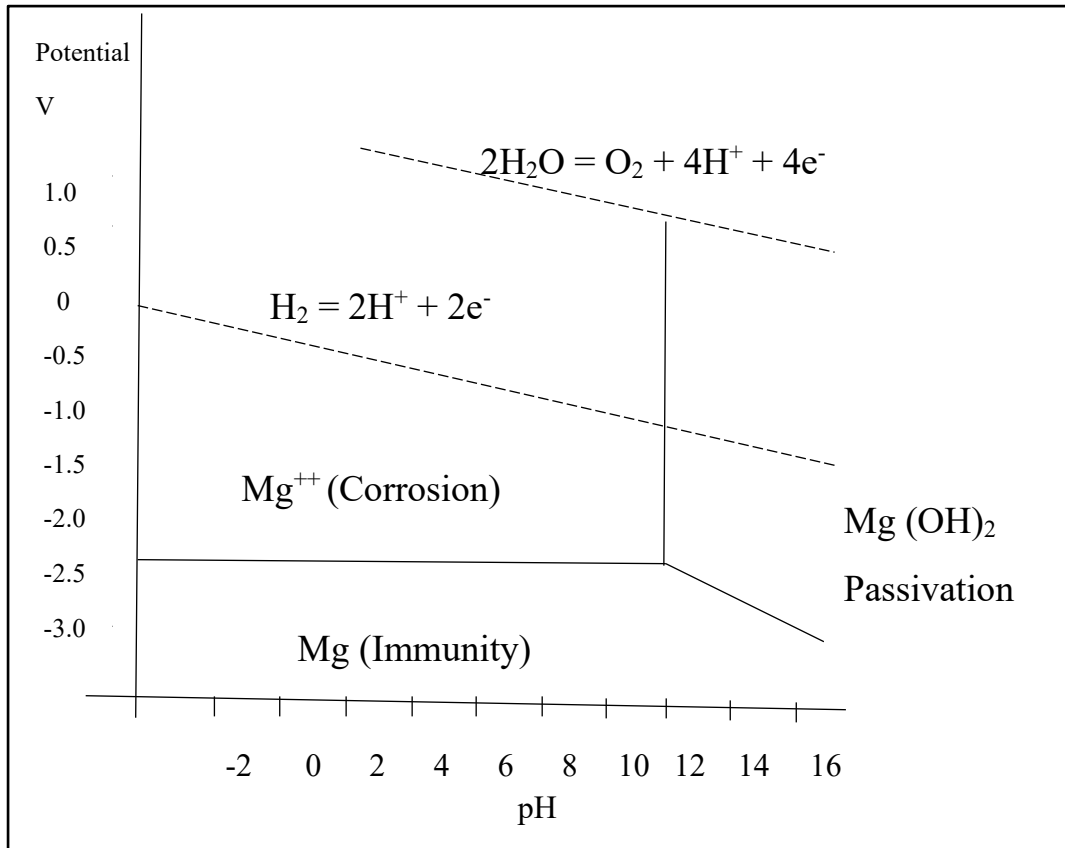

Fig. 1.1: Pourbaix diagram of magnesium and water system at 25 °C, showing the theoretical domains of corrosion, immunity, and passivation (Pourbaix 1974).

1.6 CORROSION KINETICS

Corrosion kinetics deals with the rate of the corrosion reaction, which in turn is dependent on the rate of the reactions taking place at the anodic and cathodic regions. The kinetics of the reaction taking place on the electrode surface is dependent on the electrode potential. Thus, electrode kinetics is the investigation of reaction rates at the interface between an electrode and a fluid. The study of electrode kinetics has made conceivable advances in the perception of corrosion and the functional estimation of corrosion rates. The understanding of corrosion, forms by superimposing electrochemical fractional procedures was created by Wagner and Traud (Tsai et al. 1998). Some of the significant factors related with the electrode kinetics are presented in this part.

1.6.1 Polarization

Electrode polarization can be defined as the extent of deviation of electrode potential from equilibrium value, resulting from a net current flowing from or to the electrode surface. An electrochemical reaction is said to be polarized when the reaction is retarded by chemical, physical or environmental factors. Hence polarization is also referred to as reaction inertia. Electrode polarization reduces the overall potential difference between two half cells. Hence decreases the electrochemical corrosion. The degree of polarization is called overvoltage or overpotential given by the following equation:

$$\text{Overvoltage} = E - E_0 \quad (1.9)$$

where E is the electrode potential for some condition of current flow and E_0 is the electrode potential for zero current flow at equilibrium (also termed as the open circuit potential (OCP), corrosion potential, rest potential).

Depolarizers added to the corrosion medium increase corrosion rate. Chelating ligands act as anodic depolarizers and oxidizers like ferric ions or O_2 act as cathodic depolarizers (McCafferty 2010).

1.6.1.1 Activation polarization

Activation polarization usually is the controlling factor during corrosion in a media that contains a high concentration of active species. Activation polarization refers to an electrochemical process that is controlled by the slowest step of the reaction sequence taking place at the metal-electrolyte interface. In other words, activation polarization is caused by a slow reaction of the electrode because the reaction at the electrode requires activation energy. Both anodic and cathodic reactions can be under activation polarization. A reaction for which an activation polarization predominates is referred to as 'activation controlled'.

1.6.1.2 Concentration polarization

Concentration polarization refers to an electrochemical process controlled by the diffusion in the electrolyte bulk rather than at the interface. Concentration polarization is said to be cathodic when the electrons accumulate at the cathodic interface due to the

slow diffusion of the reducing species from the bulk electrolyte to the cathode surface. Anodic polarization arises due to the slow diffusion of metal ions from the anodic interface into the bulk electrolyte. Cathodic concentration polarization usually is the controlling factor during corrosion in a media that contains a scarce amount of reducible species or oxidizers (e.g. diluted acids and aerated salt solution). Any electrochemical process where agitation leads to an increased rate of reaction is controlled by concentration polarization.

1.6.1.3 Ohmic Polarization

Electrolyte solutions have relatively lower conductivities in comparison with metals, particularly in dilute solutions. The potential drop due to the resistance of the electrolyte solution is referred to as ohmic polarization. In corrosion systems, if the metal surface is secured with paint or other protecting materials or the electrode has high resistance, they also contribute to ohmic polarization.

1.6.1.4 Exchange current density

Exchange current density is the rate of exchange reactions or redox reactions expressed in terms of current density, for electrochemical equilibria involving the participation of electrons. At equilibrium,

$$r_{ox} = r_{red} = \frac{i_0}{nF} \quad (1.10)$$

where r_{ox} and r_{red} are the equilibrium oxidation and reduction rates and i_0 is the exchange current density; n and F are no of electrons involved and Faraday in coulombs.

Some factors influencing the exchange current density are mentioned below.

- Ratio of the concentration of oxidized to reduced species at the electrodes.
- Temperature of the medium. Higher the temperature higher will be i_0 .
- Electrode surface roughness. The greater the roughness of the electrode surface, more will be the surface area, hence the higher will be i_0 . Example: platinized platinum has higher i_0 for hydrogen evolution than platinum.

1.6.1.5 Mixed potential theory

The concepts utilized in the mixed-potential theory were known in the 19th century. The concepts of this theory were formally presented by Wagner and Traud in 1938. This theory consists of two postulates:

1. Two or more partial redox reactions are involved in an electrochemical reaction.
2. In an electrochemical reaction, there can not be any net accumulation of electric charge.

The first postulate is self-evident, as electrochemical reactions are made up of at least two half-cell reactions of oxidation and reduction. The second postulate is similar to the statement of the law of conservation of charge. That is, a metal immersed in an electrolyte can not immediately collect an electric charge. From this, it follows that during the corrosion of an electrically detached metal sample, the total rate of oxidation must be equal to the rate of reduction (Fontana 2005).

1.7 ELECTROCHEMICAL CORROSION TESTING

Corrosion testing is divided into three types of classifications: 1) Laboratory tests, 2) Pilot-plant tests, 3) Tests in fields, i.e, on-site tests.

The main justifications for corrosion testing are:

- Evaluation and selection of materials for a specific environment or a given definite application.
- Evaluation of new or old metals or alloys to determine the environments in which they are suitable.
- Control of corrosion resistance of the material or corrosiveness of the environment.
- The study of the mechanisms of corrosion or other research and development purposes. These tests usually involve specialized techniques, precise measurements, and precise control.

Though numerous corrosion testing methods are available, the selection of the method is based on the type of the metal and the form of corrosion. Each of the corrosion testing

methods finds its application either in the laboratory or in the on-site field. Among the methods used, only electrochemical methods provide insight into the mechanism of corrosion. As corrosion is electrochemical in its nature, electrochemical testing methods are precise in determining its rate (Barnartt 1969).

The corrosion measurement techniques are classified into two types.

- a) DC electrochemical monitoring techniques
- b) AC electrochemical monitoring techniques

1.7.1 DC Electrochemical monitoring techniques

These methods include changing the potential of the working electrode and estimating the current delivered as a function of time or potential. When the electrode is polarized, it can cause electrochemical reactions at the electrode surface. The amount of current produced during these reactions is controlled by the kinetics of the reactions and the diffusion of reactants both towards and away from the electrode.

DC polarization technique utilizes a typical three-electrode system. The metal sample under study is made as the working electrode. An inert metal like platinum constitutes the auxiliary electrode. The potential of the working electrode is measured with reference to the reference electrode such as the saturated calomel electrode (Thompson and Payer 1998).

1.7.1.1 Tafel Extrapolation Technique

In the Tafel extrapolation method, the working electrode would be immersed in the electrolyte and then allowed to attain the steady-state potential or the OCP using an electrochemical workstation. On attaining the OCP, the system will be drifted away from its steady-state both anodically and cathodically to the OCP. A plot of the logarithm of corrosion current density against the potential thus obtained is called the Tafel plot. The straight line of anodic and cathodic branches are extrapolated such that their intersection point defines OCP at Y-axis and corrosion current density (i_{corr}) at the X-axis. However, to ensure accuracy, the linear region at least ± 50 mV from the OCP and one decade of linearity is considered to ensure good accuracy in the measurements. The corrosion potential (E_{corr}) is a thermodynamic parameter that is specific to the

sample and i_{corr} is a kinetic parameter that is directly proportional to the rate of corrosion. The anodic and cathodic Tafel slopes or constants are referred to as β_a and β_c , respectively. A representative Tafel extrapolation is depicted in Fig. 1.2.

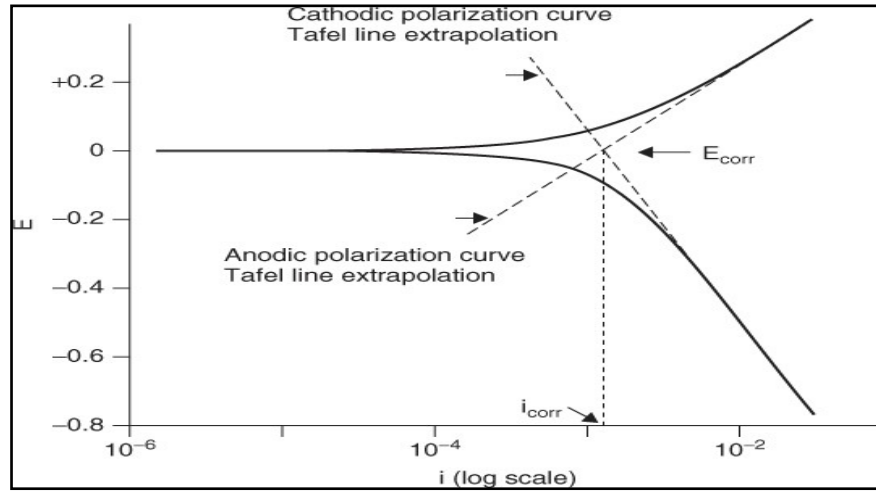

Fig. 1.2: Potentiodynamic polarization curves.

Kinetically controlled electrochemical reaction of an isolated half-cell obeys Tafel equation (1.11).

$$i = i_0 e^{\left(\frac{2.3(E-E_0)}{\beta}\right)} \quad (1.11)$$

where, i is the electrode current density of the reaction, i_0 is exchange current density, E is the electrode potential, E_0 is the equilibrium potential, β is the Tafel constant for a given reaction expressed in units of volts/decade. The combined Tafel equations for both the anodic and cathodic reactions of a corroding system generate the Butler-Volmer equation (2).

$$i = i_a + i_c = i_{corr} \left[e^{\left[\frac{2.3(E-E_0)}{\beta_a}\right]} - e^{\left[\frac{-2.3(E-E_0)}{\beta_c}\right]} \right] \quad (1.12)$$

where, β_a and β_c are Tafel constants for the linear portion of anodic and cathodic Tafel branches up to 1 decade of current, respectively. Tafel constants are related to electrode kinetic parameters and are useful in the valuation of polarization resistance (R_p) as described by the Stern-Geary Equation below (3).

$$R_p = \frac{\beta_a \beta_c}{2.3 i_{corr} (\beta_a + \beta_c)} \quad (1.13)$$

The rate of corrosion is determined by the equation below (1.14).

$$v_{corr} (mmy^{-1}) = \frac{(K \times i_{corr} \times E.W)}{\rho} \quad (1.14)$$

where, constant $K=0.00327 \text{ mm g } \mu\text{A}^{-1} \text{ cm}^{-1} \text{ y}^{-1}$, defining the unit of corrosion rate mm y^{-1} , i_{corr} is the corrosion current density expressed in $\mu\text{A cm}^{-2}$, $E.W$ is the equivalent weight of the corroding specimen, ρ is the density of corroding specimen.

Advantages of Tafel extrapolation technique

- A rapid corrosion monitoring technique as compared to the conventional weight-loss method of analysis.
- Greater accuracy in determining corrosion rate, even at extremely low corrosion rates.
- Continuous corrosion monitoring in industries is facilitated by the Tafel polarization method.

Disadvantages

- The test electrode can be polarized only a limited number of times because some degree of electrode surface roughening occurs with each polarization.
- The method can be applied only to systems containing one reduction process since the Tafel region is distorted if more than one reduction process occurs.
- The system gets disturbed due to polarization of material under test by several hundred mV from corrosion potential.

1.7.2 AC electrochemical monitoring techniques

1.7.2.1 Electrochemical impedance spectroscopy (EIS)

The electrochemical interfaces are best understood when viewed from an impedance standpoint. The impedance studies of corroding systems help to characterize and analyze complex interfaces (Niu and Lee 2000). The impedance is the AC equivalent of DC resistance (R). It is the resistance offered by a circuit to the flow of AC. In impedance tests, a sinusoidal electrochemical (current or potential) perturbation considered with reference to a suitable DC condition is impressed on the system. Most corrosion investigations involve the application of a small amplitude voltage excitation which is centered on the corrosion potential and which encompasses a wide range of frequencies. Such a multiple frequency stimulation enables computation of electrode capacitance and rates of various electrochemical reactions. Small amplitude stimulation is preferred to achieve a linear or pseudo-linear response from the system. In a linear (or pseudo-linear) system, the output will be a current sinusoid at the same frequency but shifted in phase as shown in Fig. 1.3.

Fig. 1.3: Schematic representations of a pattern of waves.

An expression similar to Ohm's law gives the impedance (Z) of the system as the ratio of potential to current both expressed as functions of time, as represented in the equation below

$$Z = \frac{E_t}{I_t} = \frac{E_0(\sin\omega t)}{I_0(\sin\omega t + \varphi)} = Z_0 \frac{(\sin\omega t)}{(\sin\omega t + \varphi)} \quad (1.15)$$

where E_t and I_t are the potential and current at time t , E_o and I_o are the amplitude of potential and current signals, ω is the radial frequency, Z_o is the magnitude of the impedance and ϕ is the phase shift.

However, the impedance ($Z(\omega)$) for practical convenience is expressed in terms of real $Z'(\omega)$ and imaginary $Z''(\omega)$ components in cartesian coordinates as given in equation (1.16):

$$Z(\omega) = Z'(\omega) + Z''(\omega) \quad (1.16)$$

The impedance data are interpreted by developing different plots like Nyquist and Bode plots. On plotting Z' along X-axis and Z'' along Y-axis, Nyquist plot will be obtained. A plot of $\log(Z_o)$ along Y-axis and $\log(f)$ (frequency) along X-axis yields Bode magnitude plot, whereas Bode phase angle plot is obtained by plotting ϕ along Y-axis against $\log(f)$ taken along X-axis. On a Nyquist plot, the impedance is symbolized as a vector, the length of which corresponds to the magnitude Z_o and the angle with which the vector remains inclined to the X-axis is equivalent to ϕ . A foremost drawback of Nyquist plots is that the exact frequency at which any data point is recorded remains disguised. The Bode plots however compensate for this limitation. Representative impedance plots are shown in Fig. 1.4.

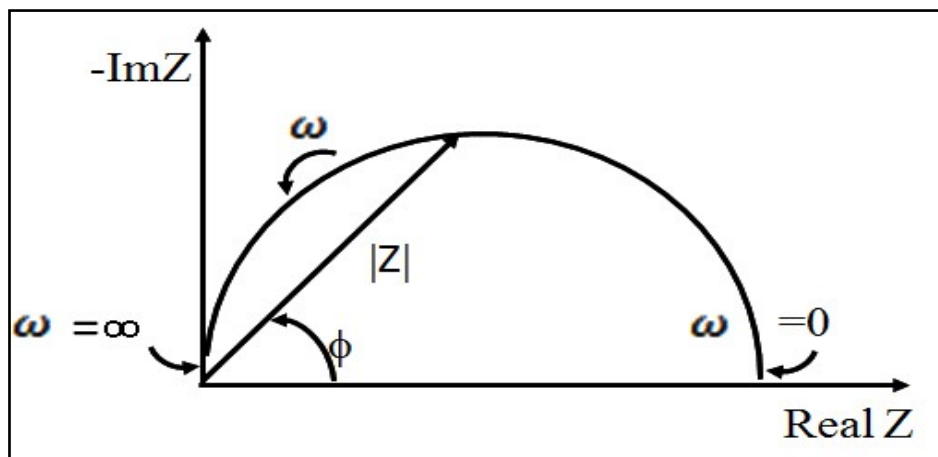

Fig. 1.4: A representative Nyquist plot.

The interpretation of impedance data is often achieved through simulation of the experimentally acquired impedance behavior with that of a suitable theoretical 'equivalent electrical circuit'.

Most of these equivalent electrical circuit models comprise various combinations of common electrical elements like resistors, capacitors, and inductors. An equivalent electrical circuit chosen for the fitment of impedance data should be such that a property related to the physical electrochemistry of the system is reflected in each of the elements in the model (Greene et al. 1961). The Nyquist plot shows a semicircle, with increasing frequency in a counter-clockwise direction as shown in Fig 1.4. At very high frequency, the imaginary component $-Z''$ disappears, leaving only the solution resistance R_s . At very low frequency, $-Z''$ again disappears, leaving a sum of R_s and the Faradaic reaction resistance or polarization resistance (R_p). The Faradaic reaction resistance is inversely proportional to the corrosion rate. R_s measured at high frequency can be subtracted from the sum of R_p and R_s .

The advantages of EIS studies are as follows:

- Non-destructive method of analysis as it operates in OCP (open circuit potential).
- Operational at extremely low corroding rates and low conductivity system.

Shortcomings of EIS are as listed below:

- A complicated method of analysis and tedious data interpretation.
- EIS alone cannot fetch sufficient data, therefore usually tested along with other measurement techniques like potentiodynamic polarization (Mansfeld et al. 1992, Laisa et al. 2017).

1.8 CORROSION CONTROL

The corrosion types are so various, and the conditions under which corrosion occurs are so different that no single strategy can be utilized to control all conceivable corrosion cases. The decision of a control strategy relies upon several factors, such as the type of the metallic structure, the application for which it is planned, the type of corrosion, and the nature of the overall condition. Some of the significant techniques used are given below (Bradford and Bringas 1993).

1.8.1 Material selection

The selected material should be such that it should be the most economic material exhibiting the best corrosion resistance against the given environment of

exposure. Pure metal or nonmetallic should be used whenever possible without compromising the desired output.

1.8.2 Alternation of environment

Changing or altering the corrosive environment gives a flexible way to decrease the corrosion rate. Ordinary changes in the medium that are regularly utilized are (1) bringing down the temperature, (2) reducing the velocity, (3) removing oxygen or oxidizers, and (4) changing the concentration of corrosive. As a rule, these progressions can fundamentally reduce corrosion, yet they should be exercised with care.

1.8.3 Mechanical design

Metallic structures ought to be planned with the end goal that there is the least possibility for any type of corrosion to occur, simultaneously without changing off any mechanical parts. There are many design rules, avoiding heterogeneity and mechanical stress are among the unmistakable ones.

1.8.4 Cathodic Protection

Cathodic protection is accomplished by providing electrons to the metal surface, making it cathodic to encompassing. It is accomplished by the galvanic coupling with a sacrificial anode or by the impressed current technique utilizing an external source of current and an inert anode. The advantage of the cathodic protection method is that the corrosion rate of cathodically protected ensured structure is not simply limited, but reduced to zero.

1.8.5 Anodic Protection

This strategy is relevant just for metals showing the active-passive transition. The metallic structure is passivated and ensured to be an anode utilizing a potentiostat. The potentiostat keeps the metal at a constant potential at which it is passivated.

1.8.6 Surface coatings

Any coating on the surface of the metal, acting as a physical barrier between the metal and the destructive corrosion medium, is useful in metal protection. Metallic, inorganic, and organic coatings have been generally applied on metal surfaces. To be

viable as a physical barrier, a surface coating ought to be persistent, uniform, impenetrable, and synthetically inactive to the corrosives and ought to have a sensibly long life.

1.9 CORROSION INHIBITORS

A corrosion inhibitor is a substance that, when added in small amounts to the corrosion environment decreases, the corrosion rate. There are various inhibitor types and classifications. Most inhibitors have been chosen by observational experimentation, and many inhibitors are exclusive in nature.

To qualify as a good inhibitor any chemical must fulfill the following requisites.

- It should be non-toxic, economically cheaper.
- It should be thermally stable and chemically inert.

The most well-known and generally known utilization of inhibitors is their application in vehicle cooling frameworks and evaporator feed water (Sastri 1998).

1.9.1 Evaluation of corrosion inhibition efficiency

Since there might be more than one inhibitor appropriate for a particular application, it is important to assess their ability to inhibit the corrosion on a metal surface. The ability of an inhibitor to protect the metal from corrosion is expressed in terms of its inhibition efficiency and is calculated using equation 1.17.

$$\eta(\%) = \left[\frac{v_{corr\ uninhib} - v_{corr\ inh}}{v_{corr\ uninhib}} \right] \times 100 \quad (1.17)$$

where, $v_{corr(uninh)}$ and $v_{corr(inh)}$ are corrosion rates in uninhibited and hindered conditions individually. The corrosion rates $v_{corr(uninh)}$ and $v_{corr(inh)}$ can be determined by any of the standard corrosion testing methods.

1.9.2 Types of inhibitors

Based on the effect of the inhibitors on the anodic reaction, cathodic reaction, or both, the inhibitors are classified as follows:

1.9.2.1 Anodic inhibitor

Anodic inhibitors are those substances that act on the anodic sites. They displace the corrosion potential (E_{corr}) in the positive direction and reduce the corrosion current (i_{corr}), thereby retard the anodic reaction and suppress the corrosion rate. Basically, oxyanions such as chromates, molybdates, tungstates, and antimonates are very effective anodic inhibitors. The anodic inhibitors combine with metal ions formed at the anodic region, forming the sparingly soluble respective salts. These compounds formed are deposited on the anodic sites forming the protective films, which act as barriers between the fresh metal surface and the corrosive medium, thereby preventing the further anodic reaction. Anodic inhibitors are found to be effective only when a sufficient amount of the inhibitor is added to the corrosion medium. When an insufficient quantity of an anodic inhibitor is added, corrosion may be more rather than inhibition.

1.9.2.2 Cathodic inhibitor

Cathodic inhibitors are those substances which act on the cathodic sites and polarize the cathodic reaction. They displace the corrosion potential in the negative direction and reduce the corrosion current, thereby retard the cathodic reaction and suppress the corrosion rate. Cathodic inhibitors may be divided into three categories, viz., (i) those that consume oxygen (deaerators or oxygen scavengers) (ii) those that reduce the area of the cathode, and (iii) those that increase the hydrogen overpotential on the cathode.

1.9.2.3 Mixed inhibitor

These are substances that affect both the cathodic and anodic reactions. Corrosion potential change in such a case is smaller. Mixed type of inhibitors is generally organic compounds that are adsorbed on the metal surface and suppress both the metal dissolution and the reduction reactions (Sastri 1998); (Tizpar and Ghasemi 2006). Based on the mechanism by which the inhibitors act, they are classified as explained as follow:

1.9.2.4 Adsorption-type inhibitors

This is the largest class of inhibiting substances. Usually, these are organic moieties that adsorb on the substrate surface and suppress metal dissolution and reduction reactions. In most cases, it appears that adsorption of inhibitors affect both the anodic and cathodic processes, although in many cases the effect is unequal.

1.9.2.5 Hydrogen-evolution poisons

These are substances such as arsenic and antimony ions, that retards the hydrogen-evolution reaction. As a consequence, these substances are very effective in acid solutions but are ineffective in environments where other reduction processes such as oxygen reduction are the controlling cathodic reactions.

1.9.2.6 Scavengers

They are the ones that act by removing corrosive reagents from the solution. Examples of this type can be sodium sulfite and hydrazine, which remove dissolved oxygen from aqueous solutions as given below

1.9.2.7 Oxidizers

These are species such as chromate, nitrate, and ferric salts that also act as inhibitors in many systems. In general, they are primarily used to inhibit the corrosion of metals and alloys that demonstrate active-passive transitions, such as iron and its alloys and stainless steels.

1.9.2.8 Vapor-phase inhibitors

These are similar to the adsorption-type inhibitors and possess a very low vapor pressure. As a consequence, these materials can be used to inhibit atmospheric corrosion of metals without being placed in direct contact with the metal surface. In use, such inhibitors are placed in the vicinity of the metal to be protected, and they are transferred by sublimation and condensation to the metal surface. These inhibitors are usually only effective if used in closed spaces such as inside packages or on the interior

of machinery during shipment. It is important to use enough inhibitors, since many inhibiting agents accelerate corrosion, particularly localized attacks such as pitting, when present in small concentrations. To avoid this possibility, inhibitors should be added in excess and their concentration checked periodically.

The mixed inhibitors inhibit the corrosion on the metal surface by one or more of the following mechanisms of inhibition.

- **Physical Adsorption:** Physical adsorption takes place through the electrostatic attraction between the dipoles of the inhibitor molecules and the charged metal surface. The physisorption process requires less activation energy and is susceptible to desorption at a higher temperature. Thus the process of physisorption is reversible in nature.
- **Chemisorption:** Adsorption that takes place due to the chemical interaction between the surface atoms of the adsorbent and the atoms of the adsorbate. This type of adsorption is known to be called chemisorption. For example, oxygen is chemisorbed by carbon, and hydrogen is chemisorbed by nickel under suitable conditions. In each case, a stable surface compound, frequently referred to as surface complex, results.
- **Film Formation:** These involve the dependence of chemical composition, their molecular structure, and their affinities for the metal surface. Because film formation is an adsorption process, the temperature and pressure in the system are important factors. Organic inhibitors will be adsorbed according to the ionic charge of the inhibitor and the charge on the surface (Gräfen et al. 2000).

1.10 MECHANISM OF CORROSION INHIBITIONS

Corrosion inhibitors influence the corrosion rate by controlling either the anodic reaction or the cathodic reaction or both. Some commonly observed mechanisms are presented in the following sections (Saji and Umoren 2020).

1.10.1 Inhibitors for acid solutions

The corrosion of metals in acid solutions can be inhibited by a wide range of substances, such as halide ions, carbon monoxide, and many organic compounds,

particularly those containing elements such as nitrogen, sulphur, phosphorus, arsenic, and oxygen. The primary step in the action of inhibitors in acid solutions is to adsorb on the metal surface, which is oxide-free in acid solutions. The adsorbed inhibitor then acts to stop the cathodic/anodic electrochemical corrosion processes.

Inhibitors of corrosion in acid solutions can interact with metals and affect the corrosion reaction in numerous ways, some of which may occur simultaneously. The mechanism of action of an inhibitor may vary with factors such as its concentration, the pH of the acid, the nature of the anion of the acid, the presence of other species in the solution, the extent of the reaction to form secondary inhibitors, and the nature of the metal.

1.10.1.1 Surface charge on the metals

Adsorption may be due to electrostatic attractive forces between ionic charges or dipoles on the adsorbed species and the electric charge on the metal at the metal-solution interface. In solution, the charge on the metal can be expressed by its potential to the zero-charge potential. As the potential of a metallic surface becomes more positive, the adsorption of anions is favored, and as the zero charge potential becomes more negative, the adsorption of cations is favored.

1.10.1.2 The functional group and structure of the inhibitor

Inhibitors can also bond to metal surfaces by electron transfer to the metal to form a coordinate type of link. This process is favored by the presence in the metal of vacant electron orbitals of low energy, such as occurs in the transition metals. Electron transfer from the adsorbed species is favored by the presence of relatively loosely bound electrons, such as may be found in anions, and neutral organic molecules containing lone pair electrons or pi-electron systems associated with multiple, especially triple bonds or aromatic rings. The inhibition efficiency increases as the electron density on the functional group increases in a series of related compounds. This is consistent with the increasing strength of coordinate bonding due to easier electron transfer and hence greater adsorption.

1.10.1.3 Interaction of the inhibitor with water molecules

Adsorption of inhibitor molecules is often a displacement reaction involving the removal of adsorbed water molecules from the surface. During the adsorption of a molecule, the change in interaction energy with water molecules in passing from the dissolved to the adsorbed state forms an important part of the free energy change on adsorption. This has been shown to increase with the increasing size of the hydrocarbon portion of an organic molecule. Thus increasing size leads to the decreasing solubility and increasing adsorbability. This is consistent with the increasing inhibitive efficiency observed at constant concentrations with increasing molecular size in a series of related compounds.

1.10.1.4 Interaction of adsorbed inhibitor species

Lateral interactions between adsorbed inhibitor species may become significant as the surface coverage, and hence the proximity, of the adsorbed species increases. These lateral interactions may be either attractive or repulsive. Interactions occur between molecules containing large hydrocarbon components. As the chain length increases, the increasing van der Waals attractive force between adjacent molecules leads to stronger adsorption at high coverage. Repulsive interactions occur between ions or molecules containing dipoles and lead to weaker adsorption at high coverage.

In the case of ions, the repulsive interaction can be altered to an attractive interaction if an ion of opposite charge is simultaneously adsorbed. In a solution containing inhibitive anions and cations, the adsorption of both ions may be enhanced and the inhibitive efficiency greatly increased compared to solutions of the individual ions. Thus, synergistic inhibitive effects occur in such mixtures of anionic and cationic inhibitors.

1.10.2 Method of inhibition in neutral solutions

Typical inhibitors for near-neutral solutions are the anions of weak acids, some of the most important in practice being chromate, nitrite, benzoate, and borate. Passivating oxide films on metals offer high resistance to the diffusion of metal ions, and the anodic reaction of metal dissolution is inhibited. The action of inhibitive anions

on the corrosion of metals in near-neutral solution involves the following important functions:

- Reduction of the dissolution rate of the passivating oxide film
- Prevention of the adsorption of aggressive anions

Inhibition in neutral solutions can also be due to the precipitation of compounds, on a metallic surface, that can form or stabilize protective films. The inhibitor may form a surface film of an insoluble salt by precipitation or reaction. Inhibitors forming film of this type include

- Salts of metals such as zinc, magnesium, manganese, and nickel, which form insoluble hydroxides, especially at cathodic areas, which are more alkaline due to the hydroxyl ions produced by the reduction of oxygen
- Soluble calcium salts, which can precipitate as calcium carbonate in H₂O containing CO₂, again at cathodic areas where the high pH permits a sufficiently high concentration of carbonate ions
- Polyphosphates in the presence of zinc or calcium, which produce a thin amorphous salt film

These salt films, which are often quite thick and may even be visible, restrict diffusion, particularly of dissolved oxygen to the metal surface. They are poor electronic conductors, and so oxygen reduction does not occur on the film surface (Yohai et al. 2011, Willumeit et al. 2011, Chou et al. 2019, Awad and Turgoose 2004).

1.11 MAGNESIUM AND ITS ALLOYS

Magnesium alloys are low-density materials with high strength to weight ratio. It is considered as a prominent material for inner closure for war ships, etc., but are limited in a wide practical application by their low corrosion resistance to the attack of electrolyte aqueous solutions. Among the structural metals, magnesium is the lightest, with a density of 1.74 g/cm³, which is nearly two-thirds that of aluminum. Magnesium alloys are often named after the synthetic method used for their manufactures, like cast alloys and wrought alloys. Despite being the lightest, the utility of magnesium alloys in weight-sensitive applications remains a challenge owing to their vulnerability to

corrosion, high-temperature creep, and flammability. Over the years all these limitations have been overcome to some extent by new alloy development using the inclusion of alloying elements that counteract these undesirable properties (Gupta and Ling 2011, Wagner et al. 2003).

1.11.1 Applications of magnesium alloys

The magnesium alloys have good demand as basic materials in structural applications, particularly in weight-critical applications. Some of the important are summarized as follows.

1.11.1.1 Application in the transport industry

Many car parts are made up of magnesium alloys. Even though they were first used in racing vehicles, later magnesium alloys parts are being used in commercial vehicles also. Magnesium-based materials are used in gearbox housing steering wheels, fuel tank cover, seat frame, airbag housing, etc (Luo and Sachdev 2012).

1.11.1.2 Military applications

The aircraft fitted with magnesium alloy parts were used during World War II. The H-19 Chickasaw helicopter, a US Army helicopter built-in 1951, contains 17% (by weight) of magnesium, a record level during its time. Examples of “military magnesium” include artillery guns, light weight personnel carrier, military aircraft like Eurofighter Typhoon, F16 and intercontinental ballistic missiles (Mathaudhu and Nyberg 2016).

1.11.1.3 Medical applications

Magnesium alloys are used in bio-implant materials. The density of Mg alloys is close to that of natural bone (1.8-2.0 g/cm³) and is lower than the competing titanium alloys. Mg alloys have a high mechanical strength compared to ceramic or polymeric biomaterials and possess greater fracture toughness. Mg ion participates naturally in human metabolism, it is the fourth most abundant cation in the human body; hence magnesium is biocompatible and nontoxic at moderate levels (Gu and Zheng 2010).

1.11.1.4 Applications in electronics

For the user, portability is highly anticipated of the electronic devices. As compared to plastic electronic materials, magnesium alloys are not only light-weight but also have better heat transfer and the ability to protect against electromagnetic and radiofrequency interferences. The magnesium components currently found in electronic devices include the housing of cell phones, digital cameras, computers, laptops, digital projectors, media players, etc.

1.11.1.5 Applications in sports

The popularity of Mg alloys as structural materials for sports equipments is not surprising considering their enviable properties such as low density, their ease of machining which facilitates the creation of complex shapes, good properties of cushioning and shock absorption, and vibration absorption. The handles of the golf club heads, tennis rackets, and mountain bike bicycle frames are some notable examples of magnesium parts in sports equipment.

1.11.1.6 Other applications

Magnesium alloys find applications in consumer products that must be lightweight for easy portability. Some examples include spectacle frames, binocular parts, and hand-held working tools for mechanical operations.

1.11.2 Magnesium alloy AZ31

AZ31 alloy is an Mg-Al alloy, which has aroused scientific interest over the last two decades. It is made up of 3 wt% of Aluminium, 1 wt% Zinc, 0.35 wt% manganese, and rest with magnesium. From a practical point of view, magnesium is the structural metal of the lowest density, which makes it highly attractive for use in the automotive, aerospace, IT, and electronics industries, as well as in the development of new biomaterials for orthopedic and cardiovascular applications where weight plays a decisive role. AZ31 alloy is a common wrought alloy that has medium strength, weldability, and good strength. This particular type of alloy comes in sheet and plate shapes. AZ31 alloy is the most widely used magnesium alloy for applications at or slightly above room temperature. Sheets made from AZ31 have been used for prototype

testing for automotive sheet panels. AZ31 sheet has similar hot deep-drawing characteristics as steel and, aluminium sheet. Magnesium alloy brackets with one rib are widely used in aircraft control systems. (Frignani et al. 2012); (Montemor 2014); (Baghni et al. 2004).

Magnesium alloys, though characterized by a low density and interesting mechanical properties, their practical applications are limited due to low corrosion resistance to the attack of aqueous solutions (Frignani et al. 2012), (Cui et al. 2008). Even if the natural magnesium corrosion products (oxides, hydroxides) tend to slow down the corrosion process by chiefly hindering the anodic oxidation reaction, the corrosion rates of these artifacts remain too high for a profitable service life (De Beni 1967), (Frignani et al. 2012). Therefore, to moderate the corrosive attacks, corrosion inhibitors may be proposed, to further decrease the corrosion rate by forming protective films or layers, either by surface adsorption or by reaction with Mg^{2+} ions.

Table 1.1: Physical and mechanical properties of AZ31 alloy.

Parameters	Value
Density ($g\ cm^{-3}$)	1.8
Melting point ($^{\circ}C$)	605-630
Electrical resistivity (ohm m)	9.2E-08
Elongation at break (%)	15
Modulus of elasticity (GPa)	45
Poisson ratio	0.35
Ultimate tensile strength (MPa)	290
Yield strength (MPa)	220

Uses

- AZ31 Mg alloy is best known for its strength, weldability, and low mass density.
- Due to its optimum physical properties and withstanding particular temperatures, it is used to produce mobile phone cases.
- AZ31 alloy is used as aircraft brackets and also used for making the backbone of aircraft as it usually comes in sheets.

- This alloy is also used in the automotive and machine-building industries for making important spare parts.
- The AZ31 Mg alloy is used in orthopedic implantations as it is a biodegradable bio-material.

1.12 LITERATURE REVIEW

1.12.1 Corrosion behavior of pure magnesium and magnesium alloys

The usage of magnesium has been limited due to its poor corrosion resistance. The resistance is very less to corrosion when it has impurities in the alloy or else exposed to strongly concentrated electrolyte species. In some cases, localized corrosion initiates corrosion in magnesium and magnesium alloys, but sometimes it is widespread and shallow. The corrosion morphology of magnesium and magnesium alloys depends on the alloy's chemistry and environmental conditions. For example, localized corrosion occurs in immersed conditions, whereas atmospheric corrosion occurs uniformly in industrial atmospheres. (Tunold et al. 1977), reported that pure magnesium was corroding trans granular and its alloys were corroding uniformly. Also, it was reported that the corrosion of pure magnesium is non-uniform, and that of its alloys are uniform (Ghali et al. 2004).

It has been thought that there are two main reasons for poor corrosion resistance in magnesium and its alloys (Shaw and Jones 1997). Initially, there is internal galvanic corrosion caused by secondary phases or impurities (Solanki et al. 2017). Secondly, the quasi-passive hydroxide film on magnesium is much less stable than the passive films which form on metals such as aluminum and stainless steels. This quasi-passivity provides only poor pitting resistance for magnesium and magnesium alloys.

The presence of impurities such as iron, nickel, and copper had attacked magnesium alloys mainly in moist conditions. In the presence of a corroding medium, these impurities act as small cathodes, creating micro-cells with the anodic magnesium matrix (Luo and Shinoda 1998).

1.12.2 Corrosion inhibitors for magnesium and magnesium alloys

Large number of chemical compounds have been synthesized and investigated for their capability to inhibit corrosion of magnesium alloys in different media. These

compounds include inorganic and organic and even the combinations of the two. Some of the best inhibitors are reported in the literature along with certain essential details are listed in Table 1.1.

Table 1.2: Eminent corrosion inhibitors for magnesium and magnesium alloys.

S.No	Inhibitor	Medium	Alloys used	Remarks	References
1	Imidazole based ionic liquids	NaCl	AZ31	Follows the Langmuir adsorption isotherm, green and sustainable	(Marya et al. 2006)
2	Sodium dodecylbenzenesulfonate (SDBS)	NaCl	AZ31 alloy	Inhibition efficiency of $0.008 \text{ mol}^{-1} \text{ L}^{-1}$ SDBS was more than 90%, Langmuir adsorption isotherm, a mixed-type inhibitor.	(Li et al. 2009)
3	Cerium(III) salts	NaCl	AM60	Formation of a thicker and more compact resistive film on the alloy sample.	(Heakal et al. 2012)
4	Sodium salt of N-lauroylsarcosine, N-lauroyl-N-methyltaurine, dodecylbenzenesulfonic acid, or sodium lauryl sulphate	NaCl and Na_2SO_4	AZ31	DBS is the most effective, precipitated layer formed, Langmuir adsorption	(Frignani et al. 2012)
5	Stearate, palmitate, and myristate	NaCl and Na_2SO_4	ZE41	Mixed type inhibition, efficiency up to 88%, obeys Langmuir adsorption	(Dinodi and Shetty 2014)
6	Sodium alginate	NaCl	AZ31	The maximum inhibition efficiency is 90.00%, at a sodium alginate	(Dang et al. 2015)

				concentration of 500 ppm.	
7	2-Hydroxy-acetophenone	Na ₂ SO ₄ , NaHCO ₃ , and NaCl	AZ91D	Below 50 ppm, the inhibition efficiency increases with the increase of in inhibitor concentration, however, with a further increase in inhibitor concentration, the inhibition efficiency decreases.	(Hu et al. 2015)
8	N,N-bis (salicylidene)-2-hydroxy-1, 3-propanediamine Schiff base	HCl	Magnesium bar	Acts as mixed-type corrosion inhibitor	(Bezaatpour and Basharnavaz 2016)
9	Sodium dodecylbenzene sulphonate (SDBS) by the addition of trisodium phosphate and sodium benzoate	Ethylene glycol	Mg-Al-Zn alloy	Predominant anodic action, Langmuir adsorption isotherm, Efficiency: 91.8%	(Medhas hree and Shetty 2018)
10	Methyl-cellulose polysaccharide	HCl	Magnesium Metal	The inhibition action follows both Langmuir and Freundlich adsorption isotherms.	(Hassan and Ibrahim 2021)

1.12.3 Strategies used for corrosion control of AZ31 magnesium alloy

The literature reveals various attempts to combat AZ31 alloy corrosion, but, the use of inhibitors has been overlooked.

Table 1.3: Strategies for corrosion control of AZ31 alloy.

Method opted	Outcome	References
Mg-Si thin film deposition	The amorphous Mg-Si film showed superior anti-seizure properties to the crystalline one because of higher hardness and Young's modulus.	(Yamaguchi et al. 2006)
Calcium phosphate coating	The coatings significantly decreased the degradation rate of the original Mg alloy, indicating that the Mg alloy with calcium phosphate coating was a promising degradable bone material.	(Cui et al. 2008)
Nanostructured cerium oxide film	Treated magnesium alloy exhibited a higher corrosive resistance than the untreated magnesium alloy.	(Ishizaki et al. 2011)
Anodised in the ionic liquid (IL) trihexyl(tetradecyl)phosphonium bis(2,4,4-trimethylpentyl) phosphinate	Film stability and corrosion protection of the AZ31 alloy increased when surfaces were anodized after an acid pickling pre-treatment in a mixture of nitric and phosphoric acid.	(Latham et al. 2012)
45S5 Glass-ceramic coatings	It was found that optimized 45S5 glass-ceramic coatings could slow down the degradation rate and decrease the mass loss of the magnesium alloy substrate from 78.04% to 2.31% in the 7 th day test, showing a good anti-	(Huang et al. 2013)

	corrosion property in a certain period.	
Schiff base	Potentiodynamic polarization curves showed that Schiff base AC inhibited both anodic and cathodic reactions at all concentrations, which indicated that it was a mixed type inhibitor.	(Thirugnanaselvi et al. 2014)
Tin Al coatings	The corrosion current density of the TinAl-coated AZ31 Mg alloy decreased from 1.066×10^{-5} A/cm ² of the control sample to 4.321×10^{-7} A/cm ² , a reduction of more than one order of magnitude	(Wang et al. 2014)
Hydrotalcite film	There were optimum values of pH, the temperature of the coating bath, and immersion time for the film formation process to achieve the best quality and corrosion resistance of the hydrotalcite film	(Chen et al. 2015)
Coated with polycaprolactone (PCL) nano-fibrous layer	Nano-fibrous PCL coating combined with prior acid treatment found to be a promising method to tailor degradation rate with enhanced bioactivity of Mg alloys	(Hanas et al. 2016)
A hybrid coating composed of dicalcium phosphate dihydrate (DCPD) and poly(lactic-co-glycolic acid) (PLGA)	The deposition time influenced the morphology and structure of the DCPD coating and consequently affected the corrosion resistance of	(Li et al. 2016)

	both the DCPD and DCPD/PLGA coated samples.	
Fluoride conversion layer (hydrofluoric acid solution and poly (L-lactic acid) (PLLA) film was prepared by spin-coating the PLLA solution)	The composite PLLA/MgF ₂ coating outperformed either of the solely applied coatings with respect to anticorrosion and adhesion properties.	(Wang and Guo 2016)
Coating DCPD	The resistance polarization was 43 times higher than non-coated.	(Zhao et al. 2016)
An inner silane-TiO ₂ coating while the top layer was composed of chitosan	The top-most biopolymer layers did not have a detrimental effect on the barrier properties of the silane-TiO ₂ coating. the corrosion mechanisms of AZ31 provided promising insights into their control via a multilayered coating.	(Cordoba et al. 2019)
Mn(NO ₃) ₂ ·4H ₂ O, Co(NO ₃) ₂ ·6H ₂ O, and polyvinyl alcohol (PVA).	Results demonstrated that the AZ31 Mg alloy sample treated by Ce-Mn-PVA showed the highest corrosion resistance. A denser Ce film with lower crack was precipitated on the sample treated by Ce-Mn-PVA conversion coating.	(Liu et al. 2021)

1.12.4 Surfactants as corrosion inhibitors

Surfactants are surface-active agents. They contain a hydrocarbon chain that points towards the metal surface phase and a hydrophilic head that points towards the aqueous phase. The amphiphilic nature of surfactant molecules creates an affinity for adsorption at interfaces such as metal/metal oxide–water interface. The adsorption of surfactant on metals and metal oxides creates a barrier that can inhibit corrosion. The

properties of surfactant and the interaction of surfactant with metal or metal oxide and the surrounding solution environments determine the level of adsorption and corrosion inhibition (Fuchs-Godec 2009; Kellou-Kerkouche et al. 2008).

Surfactant inhibitors often contain either a nitrogen or sulphur atom as part of the functional group of the molecule. Very commonly, the nitrogen atom is part of a hydrocarbon chain, and its unshared pair of electrons commonly forms a bond with metal substrates. This type of bonding often leads to bonds that are classified as chemical bonds that lead to the “chemisorption”. This type of adsorption makes it difficult for these molecules to be displaced by reactants or to allow exposure of the metal surface to the environment at the adsorption site. However, it should be noted that most metals used in corrosive environments have metal oxide surfaces that interact with surfactants differently than metals (Zhu et al. 2017).

The hydrophilic functional groups of surfactant molecules strongly prefer interaction with polar entities such as water, metals ions, and other ions. Generally, surfactants adsorb on the metal surface, block the active sites exposed to corrosive media, and thereby reduce corrosion attack.

The hydrophobic portion, which is nonpolar, strongly prefers interaction with hydrophobic entities such as the hydrocarbon phase. Therefore, surfactant molecules are prone to adsorb at and cover the surfaces/interfaces, such as air-liquid surface and liquid-solid interface, to escape from a polar solvent such as water by associating and packing hydrocarbon chains together.

Metal and metal oxide surfaces are hydrophilic. Consequently, the functional group in surfactant molecules is attracted to surfaces of metals and metal oxides. Thus, there is a driving force for surfactant adsorption on metal and metal oxide surfaces that orients the surfactant with the hydrophilic group at the solid interface and the hydrophobic hydrocarbon chain directed out into the solution, thereby creating a hydrophobic surface. This driving force causes surfactant molecules to aggregate on surfaces. If sufficient surfactant is present in solution a second layer or multiple layers of surfactant, may be adsorbed, creating a variety of adsorbed structures (Zhu et al. 2017); (Sun et al. 2018); (Aiad et al. 2010).

A broadly used corrosion control strategy is to utilize natural surfactant inhibitors, a significant number of which are surfactants with hydrophilic and hydrophobic molecules. One example of a surfactant molecule of homologous benzalkonium (BAC), hexadecyl trimethyl ammonium bromide (C_{16} , $C_{16}Cl$, or $C_{16}BzCl$), C_{16} has an N-based aromatic functional group which is hydrophilic, and a hydrophobic hydrocarbon tail with 16 linear CH_2 and CH_3 sections. This anomalous nature of surfactants determines their interactions with surfaces and interfaces.

Surfactant particles must adsorb to act as corrosion inhibitors. Adsorption relies upon the organization of the arrangement, the convergence of the adsorbate, the connection of the adsorbate with the surface, the properties of the surface and the adsorbate, and the electrochemical capacity of the surface. The sorts of natural particle adsorption are normally chemisorption, physisorption, electrostatic adsorption, and pi-bond orbital connections that have both physisorption and chemisorption properties. Inhibitors are additionally arranged into proton acceptors, electron acceptors, and mixed molecules.

Table 1.4: Surfactants as corrosion inhibitors

Surfactants	Material	Medium	references
Alkanediyl- α,ω -bis-(dimethylalkyl ammonium bromide)	Iron	HCl	(El Achouri et al. 2001)
Dodecyl benzene sulphonate	Aluminium	HCl	(Abd El Rehim et al. 2003)
Quaternaryammonium salts, three cationic surfactants and two non-ionic surfactants	Zinc	KOH	(Bereket et al. 2006)
Natrium 1,4-bis(2-ethylhexyl) sulphosuccinate	Zinc	KOH and NaCl	(Branzoi et al. 2008)

Benzoylmethyl benzimidazolium hexafluoroantimonate	Mild Steel	HCl	(Nahlé et al. 2012)

1.13 SCOPE AND OBJECTIVES OF THE PRESENT WORK

1.13.1 Scope of the work

Magnesium alloys, with low density and good mechanical properties, have the potential for their applications in diverse fields. But their uses are limited by their low corrosion resistances (Frignani et al. 2012, Cui et al. 2008). Even if the natural magnesium corrosion products (oxides, hydroxides) tend to slow down the corrosion process by chiefly hindering the anodic oxidation reaction, the corrosion rates remain too high for a profitable service life (De Beni 1967, Li et al. 2009). Therefore, to moderate the corrosive attacks, corrosion inhibitors may be proposed. For example, substances that should further decrease the corrosion current in a wider potential interval by forming far more protective films or layers maybe by surface adsorption or by reaction with Mg^{2+} ions.

The AZ31 alloy is one of the most important magnesium alloys with aluminium. Due to its low density and good mechanical properties, this structural material offers considerable potential for applications in the aerospace and transport manufacturing industries. The AZ31 alloy is used in the aircraft industry to produce flat parts with ribs, such as brackets. Though it has very good points to be considered in many fields, it is highly susceptible to corrosion in salt mediums. So far, researchers have concentrated on sol-gel treatment, coatings with organic materials etc., for corrosion prevention on AZ31 alloy. These techniques have certain drawbacks. The surface coats or films (electroplated, organic, and sol-gel) show mediocre adhesion to the alloy surface. The inhibitor addition has been popular for other alloys as an effective and economical approach for corrosion mitigation. However, the usage of inhibitors for AZ31 is quite less explored (Ishizaki et al. 2011). It can be thought that for any magnesium used technology to be triumphant, the use of efficient, green, and economic corrosion mitigation measures are indispensable. Hence the development of corrosion inhibitors for AZ31 which meet the above-laid requirements is needed now.

1.13.2 Objectives

- To study the corrosion behavior of magnesium AZ31 alloy in different media such as sodium chloride and sodium sulfate at different concentrations and solution temperatures.
- To establish the influence of pH of the media on corrosion behavior of magnesium alloy AZ31.
- To synthesize and use some organic surfactants as inhibitors and investigate their inhibition efficiency on AZ31 alloy in sulfate medium and chloride medium.
- To carry out corrosion inhibition experiments at different temperatures to evaluate the activation parameters for the corrosion process.
- To evaluate the thermodynamic parameters for the adsorption of inhibitors, and to propose the mechanism for the inhibition of AZ31 alloy corrosion, in sulfate and chloride medium.
- To correlate the theoretical DFT studies of the inhibitors with the experimental observations

1.14 OUTLINE OF THE THESIS

The thesis has been divided into four chapters. The contents of each of the chapters are summarized as follows.

Chapter 1 presents some basic aspects of corrosion, corrosion measurement techniques, corrosion control methods, and fundamental aspects of corrosion inhibitors. This chapter additionally underlines the importance of magnesium alloys as the modern auxiliary materials for weight-delicate applications. The literature survey on the corrosion of magnesium and its alloy and its inhibition has been included in the chapter. At the end of the chapter, the scope and objectives of the present work are stated.

Chapter 2 deals with the experimentation part. The methodology embraced for the preparation of the test specimen and the electrolyte medium has been explained. The section additionally presents the operative details identified with the electrochemical strategies utilized along with the calculations that have permitted to obtain the numerical results of the current work.

Chapter 3 is on results and discussions, offering an in-detail depiction of the full outcomes obtained in the study with graphical and numerical interpretations. This section fundamentally is an endeavor to explain the electrochemical behavior and corrosion inhibition of AZ31 alloy based on the investigation.

Chapter 4 sums up the work included in the thesis and lists the conclusions drawn based on experimental evidences and discussions.

CHAPTER-2
MATERIALS AND METHODS

CHAPTER 2

MATERIALS AND METHODS

2.1 MATERIALS

The investigations were performed on AZ31 Mg alloy specimen. The elemental composition of the AZ31 Mg alloy sample is given in Table 2.1.

Table 2.1: Composition of the specimen (in terms of weight%)

Elements	Weight %
Al	2.96
Zn	0.83
Mn	0.43
Si	0.004
Cu	0.004
Ni	<0.001
Fe	0.002
Mg	Balance

Preparation of test materials

Rectangular sheet-like test coupons were cut from the plate and fixed with epoxy resin so that, the area exposed to the medium was 0.69 cm². These coupons were cleaned according to standard metallographic practice, such as belt grinding followed by abrading on emery sheet, and further polishing over polishing-wheel with alumina to get a mirror finish, degreased with acetone, washed with double distilled water, and dried before immersing in the corrosion medium.

2.2 MEDIA

The media used for the investigations were sodium chloride and sodium sulfate solutions at five different concentrations.

2.2.1 Preparation of standard sodium chloride solution

Standard solutions of sodium chloride having concentrations of 0.05 M, 0.1 M, 0.15 M, 0.2 M, and 0.25 M were prepared by dissolving grade sodium chloride in double distilled water.

2.2.2 Preparation of standard sodium sulfate solution

Standard solutions of sodium sulfate having concentrations of 0.05 M, 0.1 M, 0.15 M, 0.2 M, and 0.25 M were prepared by dissolving analytical grade sodium sulfate in double distilled water.

2.2.3 Preparation of chloride and sulfate media with differing pH

The corrosion behaviour was characterized by immersing the alloy specimen in solutions of different concentrations of chloride and sulfate media. The concentrations of chloride and sulfate were kept at 0.05 M, 0.1 M, 0.15 M, 0.20 M, and 0.25 M. The pH of the solutions was adjusted to the desired values of 3, 5, 7, 9, and 11 by the addition of diluted solutions of HCl and NaOH. The chloride and sulfate solutions were prepared by dissolving analytical grade sodium chloride and sodium sulfate in distilled water.

2.3 INHIBITORS

The inhibitors, anionic Gemini surfactants, sodium 2,2'-(5,14-dibutyl-6,13-dioxo-5,8,11,14-tetraaaoctadecane-8,11-diyl)diacetate (DB), sodium 2,2'-(7,16-dihexyl-8,15-dioxo-7,10,13,16-tetraazadocosane-10,13-diyl)diacetate (DH), sodium 2,2'-(9,18-dioctyl-10,17-dioxo-9,12,15,18-tetraazahexacosane-12,15-diyl)diacetate (DO), sodium 2,2'-(11,20-didecyl-12,19-dioxo-11,14,17,20-tetraazatriacontane-14,17-diyl)diacetate (DC), sodium 2,2'-(13,22-didodecyl-14,21-dioxo-11,14,17,20-tetraazatetratriacontane-16,19-diyl)diacetate (DD) were synthesized as follows.

R (dibutylamine, dihexylamine, dioctylamine, didecylamine and didodecylamine) of about 16 mmol and EDTA anhydride (8 mmol) suspended in CH₃OH (50 mL) were reacted for 22 h at 40-45 °C.

SCHEME 1: Synthesis of anionic Gemini surfactants

The anhydride particles progressively disappeared as the reaction progressed. After cooling the sample to room temperature, the remaining particles were filtered off. The reaction mixture was evaporated to give yellowish oil. Acetone was then added until a white solid precipitated. The precipitate was filtered off and was further purified by dissolution in CHCl_3 and precipitation in acetone, to yield a white powder. Finally, the intermediate product was neutralized with sodium hydroxide (1 M aq, 2 equivalents), and the obtained solution was freeze-dried to give Gemini surfactant in quantitative yield as a colorless, hygroscopic powder. The anionic Gemini surfactants synthesized were characterized using $^1\text{H-NMR}$ (Bruker NMR spectrometer (400 MHz) with CDCl_3 as solvent and tetramethyl silane (TMS) as internal reference standard), FT-IR (Bruker, USA FT-IR spectrophotometer), and LC-MS (Agilent chromatography-mass spectrometer). The spectra are presented in Fig. 2.1 to Fig. 2.15.

2.4 METHODS

2.4.1 Electrochemical techniques

Electrochemical measurements were carried out using an electrochemical work station, Gill AC having ACM instrument Version 5 software. A conventional three-electrode system with a Pyrex glass cell was employed, with the AZ31 alloy specimen as the working electrode, a platinum counter electrode, and a saturated calomel electrode (SCE) as the reference electrode. All the values of potential reported are referred to the SCE. The polarization studies were carried out immediately after the EIS studies on the same exposed electrode surface without any additional surface treatment.

2.4.1.1 Electrochemical impedance spectroscopy (EIS) studies

Well-polished AZ31 alloy specimen coupon was exposed to the corrosion medium and allowed to establish steady-state open-circuit potential (OCP). Impedance measurements were performed at the open circuit potential (OCP) by the application of a periodic small amplitude (10 mV) ac voltage signal over a wide spectrum of frequencies ranging from 100 kHz to 0.01 Hz. The impedance data were analyzed using Nyquist and Bode plots. In all the above measurements, at least three similar results were considered and their average values have been reported.

2.4.1.2 Potentiodynamic polarization studies

The potentiodynamic current potential curves (Tafel curves) were recorded by polarizing the specimen to -250 mV cathodically and $+250$ mV anodically, relative to the OCP at a scan rate of 1 mV s^{-1} . The potentiodynamic polarization parameters were deduced by the Tafel extrapolation technique on the polarization plots.

2.4.2 Surface analysis

2.4.2.1 Scanning electron microscopy (SEM) analysis

The surface morphology of the freshly polished surface and the corroded surface of the AZ31 alloy, in the corrosive media were analyzed through the SEM images recorded using JEOL JSM-6380LA analytical scanning electron microscope. The

surface composition of the fresh surface and corroded surface were determined from their corresponding EDX spectra.

2.4.2.2 X-ray photoelectron spectrum

The corrosion product analysis was carried out by recording the X-ray photoelectron spectra of the corroded alloy surface using ULVAC-PHI, Inc; Model: PHI5000 Version Probe III spectrometer with Al K- α X-ray source.

2.4.2.3 DFT

The ground state geometry and electronic distribution of the synthesized inhibitor surfactant molecules were determined with Density Functional Theory (DFT) simulations using the Turbomole 7.2v software package. The further optimization of the geometry was done with the help of software-generated C1 point group symmetry via the B3LYP program and here, the basic set def-TZVPP was used for all the calculations. The parameters of the investigated surfactants, such as the energy of the molecule (E), the energy of the highest occupied molecular orbital (E_{HOMO}), the energy of the lowest unoccupied molecular orbital (E_{LUMO}), energy gap (ΔE), chemical hardness (η), softness (σ), ionization potential (I_p), electron affinity (E_A), electronegativity (χ), and dipole moment (μ), were calculated.

2.5 CALCULATIONS

2.5.1 Computation of corrosion rate

The corrosion current density (i_{corr}) values were deduced from the extrapolation of cathodic Tafel branches of the potentiodynamic polarization curves to the corrosion potential as the anodic curves did not have well-defined Tafel regions. The experimentally determined i_{corr} values were used in the calculation of corrosion rate (v_{corr}) using the equation mentioned below.

$$\text{Corrosion rate } (v_{\text{corr}}) = K \frac{i_{\text{corr}}}{\rho} EW \quad (2.1)$$

where, K is 3.27×10^{-3} , a constant that defines the unit for the corrosion rate, i_{corr} is the current density in A cm^{-2} , ρ is the density in g cm^{-3} and EW is the equivalent weight of the alloy. The equivalent weight for the alloy was calculated from the following equation (Dean 1999).

$$EW = \frac{1}{\sum \frac{n_i f_i}{W_i}} \quad (2.2)$$

where, f_i is the mass fraction of the i^{th} element in the alloy, W_i is the atomic weight of the i^{th} element in the alloy and n_i is the valence of the i^{th} element of the alloy. The values of f_i , W_i , and n_i , of four major elements present in AZ31, are listed in Table 2.2.

The substitution of the values in equation 2.2, gives the equivalent weight of the AZ31 alloy as 12.12.

Table 2.2: The valence, weight fraction, and atomic weight of major elements present in AZ31 alloy.

Element	n_i	f_i	W_i
Mg	2	95.78	24.30
Al	3	2.96	26
Zn	2	0.83	65.38
Mn	2	0.43	54.93

2.5.2 Calculation of inhibition efficiency

The inhibition efficiency (η) was evaluated as a function of surface coverage (θ) and the relation between the two is presented in the following equation.

$$\eta(\%) = \theta \times 100 \quad (2.3)$$

The value of θ was deduced from the results of electrochemical measurements. The i_{corr} values obtained from the Tafel polarization studies and values of polarization potential (R_p) obtained from EIS measurements were used separately in the evaluation of θ , as per the equations presented below.

$$\theta = \frac{i_{\text{corr}(b)} - i_{\text{corr}(inh)}}{i_{\text{corr}(b)}} \quad (2.4)$$

where, $i_{\text{corr}(b)}$ and $i_{\text{corr}(inh)}$ signify the corrosion current densities in the absence and presence of inhibitors, respectively.

The value of θ was evaluated from the values of R_{hf} values using equation 2.5.

$$\theta = \frac{R_{hf(inh)} - R_{hf(b)}}{R_{hf(inh)}} \quad (2.5)$$

where, $R_{hf(inh)}$ and R_{hf} signify the polarization resistances obtained in the presence and absence of inhibitors, respectively.

2.5.3 Evaluation of activation parameters

The activation parameters for the corrosion of AZ31 were calculated by measuring the corrosion rates at different temperatures. The activation parameters included apparent activation energy (E_a), apparent enthalpy of activation (ΔH^\ddagger) and entropy of activation (ΔS^\ddagger). Arrhenius law equation (Eq 2.6) was used for the calculation of E_a and the transition state equation (Eq.2.7) was employed for the calculation of ΔH^\ddagger and ΔS^\ddagger .

$$v_{corr} = Ae^{\frac{-E_a}{RT}} \quad (2.6)$$

where A is the proportionality constant which is dependent on the type of the metallic material, T is absolute temperature, R is the universal gas constant and v_{corr} is corrosion rate. The slope of the straight lines was used in the deduction of E_a (slope = $-E_a/R$).

Transition state equation:

$$v_{corr} = \frac{RT}{Nh} e^{\frac{\Delta S^\ddagger}{R}} e^{\frac{\Delta H^\ddagger}{RT}} \quad (2.7)$$

where h is plank's constant and N is Avogadro's number. The parameters ΔH^\ddagger and ΔS^\ddagger were calculated, respectively, from the slope (slope = $-\Delta H^\ddagger/R$) and intercept (intercept = $\ln(R/Nh) + \Delta S^\ddagger/R$) values of the straight lines obtained from the plots of $\ln(v_{corr}/T)$ versus ($1/T$).

2.5.4 Calculation of thermodynamic parameters

The calculation of the thermodynamic parameters for the adsorption of inhibitor were based on a suitable adsorption isotherm model with which the system under the study showed the best agreement. An adsorption isotherm is defined as a graphical representation showing the variation of extent of adsorption with pressure at a given constant temperature. For the adsorption occurring at solution/solid interface, the

concentration of the adsorbate (inhibitor) can be considered as the equivalent of pressure. The mathematical expression for the adsorption isotherms highlights an equilibrium relation between inhibitor concentrations on the metal surface and that in bulk solution. Hence the adsorption isotherms are applicable to the systems where the inhibition is the consequence of surface coverage brought about by the inhibitor on adsorption. Some of the adsorption isotherms commonly verified to explain corrosion inhibition, their mathematical expressions, and verification plots are presented in Table 2.3.

The parameters in Table 2.3 are as follows:

Table 2.3: List of adsorption isotherms.

Name	Isotherm	Verification Plot
Langmuir	$\theta/(1-\theta) = \beta.C$	C/θ vs C
Frumkin	$[\theta/(1-\theta)]e^{\theta} = \beta.C$	θ vs $\log C$
Bockris-Swinkels	$\theta/(1-\theta)^n.[\theta + n(1-\theta)]^{n-1}/n^n = C.e^{-\beta}/55.4$	$\theta/(1-\theta)$ vs $\log C$
Temkin	$\theta = (1/f)\ln K.C$	θ vs $\log C$
Virial Parson	$\theta.e^{2f\theta} = \beta.C$	θ vs $\log(\theta/C)$
Flory Huggins	$\log(\theta/C) = \log nK + n\log(1-\theta)$	$\log(\theta/C)$ vs $\log(1-\theta)$
El – Awady	$\log[\theta/(1-\theta)] = \log K + y \log C$	$\log[\theta/(1-\theta)]$ vs $\log C$

θ is the surface coverage, $\beta = \Delta G/2.303RT$, where ΔG is free energy change of adsorption, R – gas constant, T - temperature, C is inhibitor concentration in bulk electrolyte, χ represents size ratio or the number of water molecules replaced per molecule of adsorbed inhibitor, f is the inhibitor interaction parameter (0 implies no interaction; positive value implies attraction; negative value implies repulsion) and K and y are constants.

The C and θ values were graphically fitted in the adsorption isotherms to get the linear relationship between them and regression coefficients (R^2) were compared. The standard free energy of adsorption (ΔG°_{ads}) was calculated using the following expression.

$$\Delta G^\circ_{ads} = -RT \ln \left[\frac{55 \times \theta}{C(1-\theta)} \right] \quad (2.8)$$

where C is the inhibitor concentration expressed in mol.dm^{-3} and 55.5 in mol dm^{-3} is the molar concentration of water in solution.

The standard enthalpy of adsorption (ΔH°_{ads}) and standard entropy of adsorption (ΔS°_{ads}) were evaluated by making use of a rearranged form of the Gibbs Helmholtz equation, as shown below.

$$\Delta G^\circ_{ads} = \Delta H^\circ_{ads} - T\Delta S^\circ_{ads} \quad (2.9)$$

As per Equation 2.9, straight lines were obtained on graphically plotting the variation of ΔG°_{ads} with T . The slope and the intercept of the lines were, respectively, equal to ΔS°_{ads} and ΔH°_{ads} .

CHAPTER-3
RESULTS AND DISCUSSIONS

CHAPTER 3

RESULTS AND DISCUSSION

3.1 CORROSION BEHAVIOR OF AZ31 ALLOY IN AQUEOUS SALT SOLUTIONS

3.1.1 Potentiodynamic polarization measurements

The corrosion behavior of AZ31 alloy was investigated in sodium chloride and sodium sulfate media of different concentrations, at different temperatures by potentiodynamic polarization method. Fig. 3.1 represents the potentiodynamic polarization curves for the corrosion of AZ31 alloy in sodium chloride and sodium sulfate media. Similar curves have been obtained at other temperatures also.

It is seen from Fig. 3.1 that the polarization curves are shifted to the higher current density region, indicating an increase in the corrosion rate with the increase in chloride and sulfate concentration in the corrosion media. The anodic polarization curves represent the anodic oxidation of the magnesium alloy, while the cathodic curves represent the hydrogen evolution through the reduction of water at the cathode. The anodic curves show the inflection points, characterized by two different slopes, indicating a kinetic barrier effect, possibly due to the deposition of a surface film of magnesium hydroxide, followed by its dissolution at higher anodic potential (CHENG et al. 2009). It is also observed from Fig. 3.1 that there is no significant change in the overall shapes of the Tafel branches with the varying salt concentration in the corrosion media, indicating that medium concentration only alters the rate, without altering the mechanism of corrosion reaction. Such kinds of results have been reported by Nandini et al. (2014) (Dinodi and Shetty 2014) for ZE41 alloy and by Wang et al. (2010) for Mg-Al-Pb alloy. The corrosion current density (i_{corr}) was deduced by extrapolating the cathodic branch of the polarization curves to the OCP. The electrochemical polarization parameters like corrosion potential (E_{corr}), corrosion current density (i_{corr}), and cathodic slope (β_c) were obtained from the

curves. Equation (Eq. (3.1)) given below was used to determine corrosion rate in mm y^{-1} (Standard 2006).

$$v_{\text{corr}}(\text{mm y}^{-1}) = \frac{K \times i_{\text{corr}} \times EW}{\rho} \quad (3.1)$$

where constant $K = 0.00327$, defines the unit of corrosion rate (mm y^{-1}), i_{corr} is the corrosion current density in $\mu\text{A cm}^{-2}$, ρ is the density of the corroding material and EW is the equivalent weight of the alloy.

The potentiodynamic polarization parameters, including corrosion potential (E_{corr}), corrosion current (i_{corr}), cathodic slopes (β_c), and corrosion rate (v_{corr}) are summarized in Tables 3.1 and 3.2 for the corrosion of AZ31 alloy in NaCl and Na₂SO₄ media, respectively. It is evident from the data in Tables 3.1 and 3.2, that the corrosion rate increases with the increase in the concentration of chloride/sulfate in the corrosion medium. These ions are corrosive towards magnesium and its alloys because they tend to cause surface film breakdown by the dissolution of the deposited corrosion product, thereby increasing the anodic dissolution of the alloy.

Fig. 3.1: Potentiodynamic polarization curves for the corrosion of AZ31 alloy in different concentrations of a) NaCl medium at 50 °C and b) Na₂SO₄ medium at 40 °C.

3.1.2 Electrochemical impedance spectroscopy studies

The electrochemical impedance spectra in the form of Nyquist plots for the corrosion of AZ31 alloy in NaCl and Na₂SO₄ solutions of different concentrations, at 50 °C and 40 °C are presented in Fig. 3.2, respectively. Similar plots were obtained at other temperatures also.

All the Nyquist plots consist of two capacitive loops at the higher and the medium frequencies, and the beginning of an inductive loop at the lower frequency region. The higher frequency (*hf*) semicircle corresponds to the charge transfer of corrosion process and oxide film effects, and the medium frequency (*mf*) semicircle corresponds to the mass transport (diffusion of magnesium ions) through the corrosion product layer of Mg(OH)₂. The relaxation of surface adsorbed species like Mg(OH)⁺ and Mg(OH)₂ is considered to be the genesis of the lower frequency (*lf*) inductive loop. Though there are different versions of interpreting the impedance of magnesium alloy corrosion processes, the current explanation has been one of the most adopted (Mathieu et al. 2002; Song and Atrens 2007; Ardelean et al. 2008; Frignani et al. 2012). It is observed from Fig. 3.2 that the diameter of the capacitive loops decreases with the increase in the concentrations of chloride ions and sulfate ions, respectively, implying that the corrosion rate increases with an increase in the concentrations of these ions.

Fig. 3.2: Nyquist plots for the corrosion of AZ31 alloy in different concentrations of a) NaCl medium at 50 °C and b) Na₂SO₄ medium at 40 °C.

The impedance parameters obtained are derived from simulation analyses. The impedance data points excluding the *lf* inductive loop can be analyzed using an equivalent electrical circuit (EEC) along with the representative simulation plot as shown Fig. 3.3. The entire impedance studies were carried out using simulation analyses to obtain the parameters, and the measurement error was kept below 5%. The *hf* region of the impedance spectra can be simulated by a series of two parallel resistance – constant phase element (R-CPE) networks; consisting of the charge transfer resistance (R_{ct}) in parallel with the double layer CPE (Q_{dl}) and the surface film resistance (R_f) in parallel with the CPE (Q_f) of the film. The *mf* response can be simulated with a parallel network of resistance (R_{dif}) with the CPE (Q_f) of the film. The *mf* response can be simulated with a parallel network of resistance (R_{dif}) and CPE (Q_{dif}) associated with the diffusion (Fletcher 1994). The constant phase element (Q_{dl}) is substituted for the ideal capacitive element in order to account for the inhomogeneity and porosity of the electrode surface (Mansfeld et al. 1992).

Fig. 3.3: Simulation curve and electrical equivalent circuit used for the simulation of experimental data for the corrosion of AZ31 alloy in 0.20 M NaCl medium.

The impedance of the constant phase is given by the following equation (Dinodi and Nityananda Shetty 2013):

$$Z_Q = Y_0^{-1}(j\omega)^{-n} \quad (3.2)$$

where Y_0 is the CPE constant, ω represents the angular frequency (in rad s^{-1}), $j^2 = -1$ is the imaginary number and n is a CPE exponent which measures the heterogeneity or roughness of the surface. The value of n is given by ($-1 \leq n \leq 1$); and the CPE simulates an ideal capacitor when $n = 1$, an ideal inductor for $n = -1$, and an ideal resistor for $n = 0$. The capacitance is deduced from the CPE using the following equation (Pebere et al. 1990):

$$C = Y_0(\omega_{max})^{n-1} \quad (3.3)$$

where, ω_m^n is the frequency at which the imaginary part of the impedance (Z'') has a maximum.

The values of electrochemical impedance parameters are listed in Tables 3.3 and 3.4 for the corrosion of AZ31 alloy in NaCl medium and Na₂SO₄ medium, respectively. The impedance value is inversely related to the corrosion rate. The decrease in the values R_{hf} with the increase in the concentration of chloride and sulfate ions indicates the increase in the corrosion rate. The trend is in line with the one observed in the case of potentiodynamic polarization studies. The trend can be explained by taking into account of the tendency of anions like sulfate and chloride to destabilize the Mg(OH)₂ surface film by dissolution when they are present in higher concentrations in the corrosion media, thereby negating the partial protection provided by the surface film of the corrosion product.

3.1.3 Influence of temperature

The effect of temperature on the corrosion of AZ31 alloy in the chloride and the sulfate media of different concentrations were evaluated by measuring the corrosion rates at different temperatures. Fig. 3.4 shows the potentiodynamic polarization curves for the corrosion of AZ31 alloy at different solution temperatures, in 0.25 M NaCl and 0.15 M Na₂SO₄ solutions. The Nyquist plots for the same are shown in Fig. 3.5.

Fig. 3.4: Potentiodynamic polarization curves for the corrosion of AZ31 alloy in a) 0.25 M NaCl and b) 0.15 M Na₂SO₄ at different temperatures.

Fig. 3.5: Nyquist plots for the corrosion of AZ31 alloy in a) 0.25 M NaCl and b) 0.15 M Na₂SO₄, at different temperatures.

It can be observed from Fig. 3.5 that the increase in medium temperature makes the polarization curves to shift towards a higher current density region and capacitive loops in the Nyquist plots to decrease its diameter, both of which signify an increase in the rate of corrosion. The influence of temperature is rather apparent from the variation in the electrochemical parameters enlisted in Table 3.3, Table 3.4, wherein both sodium chloride and sodium sulfate media, at any concentration, the rate of AZ31 corrosion increases with the increase in the temperature. Furthermore, at any specific medium concentration, the thickness and the protective performance of the surface film are optimal at lower

temperatures, as precisely reflected by the combination of values; smaller C_f , and larger R_f , which is observed only at lower temperatures.

Fig. 3.6: Arrhenius plots for the corrosion of AZ31 alloy in a) NaCl and b) Na₂SO₄ media.

The activation energy corresponds to the energy barrier for the occurrence of corrosion. The continuous decrease in E_a with the increased ionic concentration of the media as seen in Table 3.5 and Table 3.6, points out that the corrosion of AZ31 is energetically more feasible in concentrated media (Baghni et al. 2004).

Fig. 3.7: $\ln(v_{corr}/T)$ vs. $1/T$ plots for the corrosion of AZ31 alloy in a) NaCl and b) Na₂SO₄ media.

The pattern of variation of ΔH^\ddagger values is identical to that of activation energy. The negative values of ΔS^\ddagger suggest a decrease in the randomness of the

system which could be the consequence of the association of the reactants during the formation of the activated complex in the rate-determining step of corrosion (Bentiss et al. 2005).

The study of corrosion in a range of temperatures is good in some ways; not only does it establish the impact of temperature on the corrosion rate but also facilitates the evaluation of activation parameters pertaining to the alloy dissolution. Arrhenius law equation (Eq. 2.7) and transition state equation (Eq. 2.8) as stated in the previous chapter, were utilized for the determination of activation energy (E_a), the enthalpy of activation (ΔH^\ddagger), and entropy of activation (ΔS^\ddagger). Arrhenius plots for the corrosion of AZ31 alloy specimen in sodium chloride and sodium sulfate media are represented in Fig. 3.6. The $\ln(v_{corr}/T)$ versus $(1/T)$ plots for the same are shown in Fig. 3.7.

3.1.4 Mechanism of AZ31 alloy corrosion

3.1.4.1 Anodic dissolution of magnesium and negative difference effect [NDE]

The corrosion behavior of magnesium and its alloys is accompanied by high hydrogen evolution and the reaction rate increases with the increase in the anodic polarization. This is called a negative difference effect (Song et al. 1998). Many models have been suggested to explain this effect. The removal of a protective film surface with anodic polarization must make up the diminution of the cathodic current density by anodic polarization.

The chosen medium NaCl and Na₂SO₄ for the present study are both near-neutral solutions, where the cathodic reaction of corrosion dominates and where the corrosion happens due to the hydrogen evolution through electrochemical reduction of water as shown below.

However, the anodic oxidation of magnesium dissolution has remained complex. The oxidation and the corresponding corrosion of magnesium in an

aqueous solution can be represented by the following reactions (Baghni et al. 2004):

The steady-state working potential of magnesium is about -1.5 V, even though the standard electrode potential of magnesium is -2.38 V. The change in potential is due to the formation of $Mg(OH)_2$ film on the surface of the alloy (Mathieu et al. 2002). However, this hydroxide layer is discontinuous and only partially covers the alloy surface, without effectively protecting the alloy surface. The anodic dissolution of magnesium and its alloys involve two oxidation processes. At more active potentials of about -2.78 V (vs SCE) magnesium undergoes oxidized to monovalent magnesium ion (Mg^+) and at slightly higher potentials of about -1.56 V (vs SCE), magnesium undergoes oxidation to a divalent magnesium ion (Mg^{2+}), in parallel with the former oxidation (Lopez and Natta 2001). The monovalent magnesium ion is unstable and undergoes oxidation to divalent magnesium ion through a series of reactions involving unstable intermediates like magnesium hydride as shown in equations below:

The involvement of intermediates like monovalent magnesium ions during AZ31 corrosion is substantiated by the appearance of the inductive loops at the lower frequency region in the Nyquist plots. The secondary oxidation eventually produces hydrogen (evolved via chemical oxidation) and magnesium hydroxide as represented in the eqn. 3.10 (Song and Atrens 1999).

Thus, during corrosion of magnesium and its alloy in an aqueous solution, the hydrogen evolution takes place in both cathode and anode,

respectively, through electrical reduction and chemical oxidation of Mg^+ and Mg^{2+} . The product formed by corrosion, i.e., $Mg(OH)_2$ precipitates and forms over the corroding magnesium surface as a film. The film is very feeble and thin with a Pilling Bedworth ratio of 0.84 (Zhao et al. 2008). The efficacy of the surface film to protect the underlying metal is believed to be inadequate and hence the magnesium hydroxide surface film has been termed as partially protective where the corrosion reactions continue unabatedly within the defects of the film (Nordlien et al. 1997).

Many different ways have been put forward to clarify negative difference effects in the literature review of the introduction; such as 1) univalent magnesium ion (Mg^+) model, (2) eroding and tearing away of cathodic secondary phase particles due to micro galvanic corrosion, (3) hydride model, (4) feeble protective film model. These models try to discuss the NDE in their aspects. The univalent magnesium ion model and hydride model corroborate the chemical evolution of hydrogen. The second aspect of NDE explains that the untimely and accelerated anodic dissolution results due to the breakdown and dissolution of the surface film at higher anodic overvoltages as predicted by the partially protective film model.

3.1.4.2 Microgalvanic corrosion of AZ31 alloy

AZ31 is a wrought alloy, where its microstructure is pivotal in the corrosion of its alloy. The microstructure of AZ31 alloy consists of the α -Mg matrix, distributed with the secondary β -phase, comprising of intermetallic compound $Mg_{17}Al_{12}$. The secondary β -phase is cathodic to the Mg matrix and is with a good passive behavior over a broad range of pH (CHENG et al. 2009). However, the role of β -phase in the corrosion process depends upon its size and distribution (Dinodi and Nityananda Shetty 2013). When the grain size of magnesium alloy is small and the mass fraction of β - phase is high, the distribution of the β -phase on the α -Mg matrix is continuous; providing corrosion protection by a barrier layer effect. On the other hand, when the grain size is larger and the β -phases cannot cover the α -phase completely, galvanic corrosion results with the α -phase acting as anode and undergoing corrosion.

The corrosion product, $\text{Mg}(\text{OH})_2$, precipitates over the α -Mg matrix and this surface film is only partially selective as the continuity of the film is interrupted by the presence of the secondary phase. In addition, the secondary oxidation results in the chemical liberation of hydrogen gas at the anode. This rapid liberation of hydrogen gas at the anodic sites causes the breakdown of the surface film at higher anodic overvoltage and accounts for the inflection in an anodic branch of Tafel plots (Nordlien et al. 1997).

Choi (Choi and Pyo 2016) investigated the corrosion of several magnesium alloys in aqueous salt solutions and have highlighted the difference between the corrosion rates obtained from the Tafel extrapolation (short-term method) and other non-electrochemical methods like hydrogen evolution studies and weight-loss measurements (long-term methods). In Tafel measurements, the corrosion rate determination is based upon the rate of electron transfer or the current density. The polarization measurements when performed soon after the immersion of the alloy in the electrolyte give instantaneous corrosion rates. The corrosion rates were examined using hydrogen evolution studies for exposure periods until a steady state was obtained. Considering the dynamic nature of the interface of corroding alloy, the immediate and steady-state corrosion rates are meant to differ as to the surface topography and the corroding area continuously change with time (Lv et al. 2014; King et al. 2014; Chen et al. 2019). The potentiodynamic polarization measurements for AZ31, even when performed after the attainment of the steady-state, might differ from those obtained through hydrogen evolution tests and other techniques, considering the features of negative difference effect. Since magnesium corrosion is only partly electrochemical, hydrogen is evolved both electrically through cathodic reduction and chemically through secondary oxidation; the rate of evolution of hydrogen calculated from the hydrogen evolution studies might overestimate the actual rate of alloy corrosion. The discrepancy with the results of weight loss measurements is because of the after-effects of micro-galvanic corrosion, where the cathodic intermetallic particles fall out of the alloy due to accelerated dissolution across the particle boundary. Such undermining and falling away of

the cathodic particles results in a weight loss that is larger than that arising solely from the electrochemical metal alloy dissolution.

3.1.4.3 Influence of ionic concentration and temperature

The response of the AZ31 alloy towards the changes in the environmental factors like ionic concentration or temperature to a great measure is influenced by the surface film properties, especially the film stability. The dissolution of the film layer exposes the naked alloy surface to the electrolyte, resulting in an accelerated attack. The protective performance of the surface film is primarily dependent on the electrolyte type. The anions like chloride and sulfate which act as pitting agents bring about the dissolution of the surface film by transforming magnesium hydroxide into soluble salts of magnesium chloride and magnesium sulfate respectively (CHENG et al. 2009). The outcome of this surface film dissolution paves way for an increase in the corrosion rate of the AZ31 alloy as there is an increase in the concentration of ionic media.

Normally chloride will be significantly more corrosive than sulfate for both Mg and Al (Zhao et al. 2008a). In the NaCl environment, the adsorption of the chloride ions on the Mg surface effectively changes Mg(OH)₂ to soluble MgCl₂, thus destroying the compactness of the corrosion product film and resulting in pitting corrosion (Song and Atrens 1999). It is expected that magnesium dissolution and hydrogen evolution rates in NaCl medium should be higher than that in Na₂SO₄ medium and the experimental results in the present study are consistent with the trend expected. The chloride ions not only increase the solubility of magnesium oxide or magnesium hydroxide surface film significantly, its combination with metallic magnesium, weakens the bonds among the metallic atoms and quickens their take-off from their original position to form the intermediate species Mg⁺ (Jia'an et al. 2017). Also, in the presence of sulfate ions Mg-Al alloys form MgAl₂(SO₄)₄.22H₂O as per the following equation (3.11):

The so formed $\text{MgAl}_2(\text{SO}_4)_4 \cdot 22\text{H}_2\text{O}$, as a corrosion product gets deposited on the surface of the alloy, due to its lower solubility, forming a semi-permeable film on the alloy surface. This decreases the penetration of sulfate ions. Also, sulfate ion is bigger than chloride ions in size, and hence, less prone to drill through the film. Thus, both these factors reduce the penetration of sulfate ions to the fresh alloy surface (Iwanaga et al. 2004).

The corrosion rate of AZ31 alloy from the results of this study shows that the increase in the corrosion rate is accompanied by an increase in temperature. The temperature effects can be assigned to the increase in the dissolution of the surface film and decreased hydrogen overvoltage. The solubility of $\text{Mg}(\text{OH})_2$ increases with the increase in the temperature and hence a higher solution temperature promotes greater dissolution of the surface film. The increase in temperature is also known to increasingly reduce the hydrogen overvoltage which makes the cathodic hydrogen evolution and the alloy corrosion occur easily.

3.1.5 Surface morphology

The SEM images were used to compare the morphology of the alloy surfaces under un-corroded and corroded conditions. EDX was employed to evaluate the compositions of the respective alloy surfaces. The SEM image of the freshly polished surface of AZ31 alloy is shown in Fig.3.8 The microstructure of the alloy, as evident from the SEM image, consists of randomly distributed sub-micron sized β -phase in the main body of the α -phase. The average grain size was obtained to be 2.8 μm . The EDX spectra (Fig. 3.9) of the freshly polished surface shows the presence of the constituent elements of the alloy. The SEM image of the alloy surface immersed in 0.1 M, 0.15 M, 0.20 M, and 0.25 M NaCl medium for 3 h is shown in Fig. 3.10. The EDX spectra of the alloy surface immersed in 0.25 M NaCl is shown in Fig. 3.11. The SEM image of the alloy in 0.1 M, 0.15 M, 0.20 M, and 0.25 M Na_2SO_4 and EDX spectra of the alloy surface after immersion in 0.2 M Na_2SO_4 medium for 3 h are presented in Figs. 3.12 and 3.13, respectively. The SEM images of the alloy surfaces clearly show the deterioration in the presence of the corrosive media;

the microstructure is hardly visible hinting at the deposition that occurred on the surface as a film. The appearance of predominant oxygen on the alloy surface due to the presence of corrosion product, $\text{Mg}(\text{OH})_2$ on the surface.

3.1.6 Summary

- The environmental factors like temperature, concentrations of sulfate and chloride ions in the corrosion media and temperature have a significant influence on the rate of corrosion of magnesium alloy AZ31.
- The corrosion rate of AZ31 alloy increases with the increase in temperature and ionic concentration.
- The results for electrochemical studies in combination with surface analysis confirm the formation of Mg(OH)₂ film on the corroding alloy surface.
- The Mg(OH)₂ surface film is partially protective due to imperfections like breaks and non-uniformity. Higher ionic concentrations and temperatures further destabilize the surface film possibly by dissolution and increase the corrosion rate.
- The corrosion kinetics follows Arrhenius law.
- The rate of corrosion of the alloy is higher in the chloride medium than in the sulfate medium.

3.2 INFLUENCE OF pH ON THE CORROSION OF AZ31 ALLOY IN AQUEOUS SALT SOLUTIONS

3.2.1 Potentiodynamic polarization measurements

The potentiodynamic polarization curves for the corrosion of AZ31 alloy in 0.1 M NaCl and 0.1 M Na₂SO₄ at pH 3, 5, 7, 9, and 11 are presented in Fig. 3.14. Similar plots were obtained in solutions of other concentrations with respect to NaCl and Na₂SO₄. The influence of the medium pH plays an important role in the corrosion of AZ31. The potentiodynamic polarization curves for the corrosion of AZ31 alloy in solutions of different pH show that the polarization curves shift to the higher current density region, implying an increased corrosion rate as the medium pH decreases from highly alkaline (pH=11) to highly acidic (pH=3) conditions (Acharya and Shetty 2019). The cathodic branches of the polarization curves were extrapolated to the open circuit potential to obtain the corrosion current density (i_{corr}), as the anodic curves do not possess distinct Tafel regions.

The results summarised in Table 3.7 and Table 3.8 indicate that a higher corrosion rate is associated with a lower medium pH in all the corrosion media containing different concentrations of chloride ions or sulfate ions. Also, the corrosion rate increases with the increase in the concentrations of both chloride ions and sulfate ions at all the pH conditions studied. Although few authors like Zhao (Zhao et al. 2008) have studied E_{corr} associated with higher corrosion rate for alloys like ZE41 alloy, this behavior cannot be judged as a phenomenon for all magnesium alloys, since many studies carried, shows no such direct relation between E_{corr} , β_c and corrosion rate.

The stability of metallic magnesium and its corrosion product magnesium hydroxide (Mg(OH)₂) as a function of the potential and pH of aqueous solutions is shown in the potential-pH plot in the introduction part of the thesis.

The anodic reaction involves the dissolution of magnesium and the cathodic reaction is the hydrogen evolution by the reduction of water. The

liberation of hydrogen leads to the increase in the pH of the medium, lowering the solubility of Mg^{2+} and precipitating it as $\text{Mg}(\text{OH})_2$, creating a surface layer on the alloy. The so formed corrosion product $\text{Mg}(\text{OH})_2$ is stable only in alkaline conditions as shown in pourbaix diagram, with pH value above 10.5. Thermodynamically $\text{Mg}(\text{OH})_2$ is unstable at pH values below 10.5, but still magnesium can develop a partial $\text{Mg}(\text{OH})_2$ film on the surface of the metal in acidic conditions if the dissolution rate of $\text{Mg}(\text{OH})_2$ is slower than the rate of its formation. Also, due to the cathodic reaction of hydrogen generation, an alkaline pH zone develops at the electrode interface, which facilitates $\text{Mg}(\text{OH})_2$ precipitation and film formation, even when the bulk pH is acidic (Zhao et al. 2008).

By understanding the mechanism, the observed trend of the increased corrosion rate of AZ31 alloy with the decreasing pH value at every chloride and sulfate medium concentration can be justified. There is a reduced attack on the magnesium alloy surface in alkaline conditions, where $\text{Mg}(\text{OH})_2$ surface film is highly stable and protective. Lowering medium pH increases the solubility of the surface film, accounting for the increased corrosion rate observed in the acidic media. The corrosion rate observed in the basic media, is quite significant, though small. The $\text{Mg}(\text{OH})_2$ surface film formed on the surface of the alloy is thin with a Pilling-Bedworth ratio ~ 0.81 (Song and Atrens 2007) and the formed protective film is only partial and is incapable of completely covering the underlying alloy surface. Thus, the corrosion reactions take place predominantly at the breaks and imperfections of the film (Gao and Liang 2007).

The stability of the surface film also depends on the pH value of the corrosion medium. A higher pH value solution usually makes the surface film more passive. In solutions of higher pH, there is a higher concentration of OH^- available to compete with chloride ions or sulfate ions to adsorb onto the film surface, and to repel more of these anions out of the film/solution interface. This decreases the influence of the chloride ions and sulfate ions on the film.

Fig. 3.14: Potentiodynamic polarization curves for the corrosion of AZ31 alloy in a) 0.1 M NaCl and b) 0.1 M Na₂SO₄ solutions of different pH at 30 °C.

3.2.2 Electrochemical impedance spectroscopy

Fig. 3.15 presents the electrochemical impedance spectra in the form of Nyquist plots for the corrosion of AZ31 alloy at different pH conditions in 0.1 M sodium chloride medium and 0.1 M sodium sulfate medium. Similar curves were obtained in other concentrations of chloride and sulfate media.

Fig. 3.15: Nyquist plots for the corrosion of AZ31 alloy in a) 0.1 M NaCl and b) 0.1 M Na₂SO₄ solutions of different pH at 30 °C.

The decrease in the diameter of the capacitive loop denotes the increased corrosion rate with the decrease in the pH of the media, respectively. The results of EIS measurements are summarized in Table 3.9 and Table 3.10 for sodium

chloride media and sodium sulfate media, respectively. The results of EIS measurements are in line with those of potentiodynamic polarization measurements.

3.2.3 Scanning electron microscopy

The surface morphology of the alloy is often helpful in estimating the effect of a corrosive pH medium on the alloy surface. The surface morphology of the corroded alloy specimens under different conditions was analyzed by recording the SEM images of their surfaces. The SEM image and the corresponding EDX spectrum of the freshly polished surface of AZ31 alloy is shown in Fig. 3.16. The SEM images of AZ31 alloy surfaces after their corrosion in 0.2 M in NaCl medium of pH 3,7 and 11 for 3 h at 30 °C are shown in Fig. 3.17. The corresponding EDX spectrum is shown in Fig. 3.18. The SEM images of AZ31 alloy surface after their corrosion in 0.2 M Na₂SO₄ with pH 3, 7, and 11 are shown in Fig. 3.19. The corresponding EDX spectrum is presented in Fig. 3.20. The surface appears more deteriorated in the acidic pH, relatively less deteriorated in the neutral pH, and least deteriorated in the basic pH. These observations are in line with the observations of electrochemical studies.

3.2.4 Summary

- The corrosion of magnesium alloy AZ31 in Na₂SO₄ and NaCl solutions is strongly influenced by the medium pH.
- A higher corrosion rate is associated with a higher sulfate and chloride ion concentration at each pH and with a lower pH at each sulfate ion and chloride ion concentration, respectively.
- In the studied range of pH the highest rate of corrosion was exhibited by NaCl and Na₂SO₄ solution at pH value 3, and the lowest corrosion rate at pH value of 11.

3.3 SODIUM 2,2'-(5,14-DIBUTYL-6,13-DIOXO-5,8,11,14-TETRAAZAOCTADECANE-8,11-DIYL)DIACETATE (DB) AS CORROSION INHIBITOR ON AZ31 MAGNESIUM ALLOY IN SODIUM CHLORIDE AND SODIUM SULFATE SOLUTIONS

3.3.1 Potentiodynamic polarization measurements

Potentiodynamic polarization curves for the corrosion of AZ31 magnesium alloy in 0.1 M NaCl and 0.1 M Na₂SO₄ solution in the presence of different concentrations of DB, at 50 °C are shown in Fig. 3.21. Similar plots were obtained in the other five concentrations each of NaCl and Na₂SO₄ at different temperatures studied.

The potentiodynamic polarization parameters such as corrosion potential (E_{corr}), corrosion current density (i_{corr}), cathodic Tafel slope (β_c) were calculated from the Tafel plots in the presence of different concentrations of DB at different temperatures and are summarized in Tables 3.11 to 3.20.

In general, according to the results presented in Tables 3.11 to 3.20 and also from polarization curves in Fig. 3.21, the corrosion current density (i_{corr}) decreases significantly even on the addition of a small concentration of DB compound, and the inhibition efficiency ($\eta\%$) increases with the increase in the inhibitor concentration on the AZ31 magnesium alloy. The corrosion current density (i_{corr}) values were obtained by the extrapolation of cathodic branches of the polarization plots. It can be observed that both the cathodic and anodic reactions are suppressed with the addition of DB, which suggested that the inhibitor exerted an efficient inhibitory effect both on the anodic dissolution of metal and on the cathodic hydrogen liberation reaction (Li et al. 2009). Inhibition efficiency increases with the increase in the inhibitor concentration up to an optimum value. Thereafter the increase in the inhibitor concentration resulted in a negligible increase in inhibition efficiency.

As the concentration of the inhibitor increases from 0.0008 M to 0.0025 M, it is noticed that the corrosion current shifts slightly towards a lower current density. This indicates that the inhibitor promotes the passivation of AZ31 magnesium alloy through adsorption and decreases corrosion rate. The increase

in the inhibition efficiency with the increase in inhibitor concentration is attributed to the increased surface coverage by the inhibitor molecules as the concentration is increased (Zhao et al. 2008).

It is seen from the Tables, that the value of β_c does not change significantly with the increase in DB concentration, which indicates that the addition of DB does not change the mechanism of cathodic hydrogen evolution. The small change in β_c value suggests that the DB gets adsorbed on the metal surface and the addition of the inhibitor hinders the corrosive attack on the AZ31 magnesium alloy (Zeng et al. 2014).

It can also be seen from the Tables, that there is no appreciable shift in the corrosion potential value (E_{corr}) on the addition of DB to the corrosion medium and also on increasing the concentration of DB. If the displacement in corrosion potential is less than ± 85 mV with respect to corrosion potential of the blank, then it is said to be mixed type inhibitor (Dinodi and Nityananda Shetty 2014); (Cao et al. 2009). Therefore, the DB is considered to be a mixed type inhibitor.

Fig. 3.21: Potentiodynamic polarization curves for the corrosion of AZ31 alloy in the presence of different concentrations of DB in a) 0.1 M NaCl solution and b) 0.1 M Na₂SO₄ solution at 50 °C.

3.3.2 Electrochemical impedance spectroscopy

Nyquist plots for the corrosion of AZ31 magnesium alloy in 0.1 M NaCl and 0.1 M Na₂SO₄ solution in the presence of different concentrations of DB are shown in Fig. 3.22. Similar plots were obtained in other concentrations of NaCl and Na₂SO₄ and also at other temperatures. It can be observed from the figure that the diameter of the semicircle increases with the increase in the concentration of DB, indicating a decrease in the corrosion rate of the alloy sample.

The Nyquist plots display two capacitive semicircles at higher and medium frequencies, the former being much larger than the later, followed by the beginning of an inductive loop at lower frequency region. The higher frequency (*hf*) loop is the result of charge transfer of the corrosion process and surface film effects. The medium frequency (*mf*) semicircle arises as a consequence of diffusion or electrolyte ingress, through the corrosion product layer. The appearance of a lower frequency (*lf*) inductive loop is attributed to the relaxation of intermediates like Mg(OH)⁺_{ads} and Mg⁺_{ads} adsorbed at the metal surface. When compared with the blank the capacitive semicircles appear enlarged in the presence of DB. This is indicative of improved corrosion resistance of AZ31 alloy in DB containing solutions (Dinodi and Shetty 2014); (Song and Atrens 1999); (Mansfeld et al. 1992); (Ardelean et al. 2008).

The electrical equivalent circuit presented in Fig. 3.3 is fitted into the impedance data and the electrochemical impedance parameters were calculated. The electrochemical impedance parameters for the corrosion of AZ31 magnesium alloy in NaCl and Na₂SO₄ media are summarised in Tables 3.21 to 3.30. The inhibitor molecules adsorb along with the interface by replacing previously adsorbed water molecules. As a consequence, the impedance parameters are bound to change upon DB addition, as observed from Tables 3.21 to 3.30. The trend of higher η (%) at higher DB concentration is in close accordance with those obtained from the polarization measurements. On increasing the concentration of DB, R_f and R_{dif} value increases, whereas C_{dl} and C_f values decline. The increase in R_f signifies that the protection offered by the

surface film is magnified to several folds on the addition of DB into the system and R_{dif} is hindrance for the diffusion of ions through the film surface. The diminution in C_{dl} and C_f values can be the outcome of reduction in local dielectric constant and/or increased thickness of the electrical double layer and the surface film, respectively.

Fig. 3.22: Nyquist plots for the corrosion of AZ31 alloy in the presence of different concentrations of DB in a) 0.1 M NaCl and b) 0.1 M Na₂SO₄ at 50 °C.

The Bode plots of phase angle and amplitude for the corrosion of the AZ31 Mg alloy immersed in 0.1 M NaCl and 0.1 M Na₂SO₄ at 50 °C in the presence of different concentrations of DB, are shown in Fig. 3.23 and Fig. 3.24, respectively. As seen from Bode plots, both the impedance modulus (Z_{mod}) at low frequency and the phase maximum (θ_{max}) at intermediate frequency increase with the increase in DB concentration, which together points out the presence of highly protective surface film formed by the inhibitor, thereby protecting the metal surface from corrosion.

Fig. 3.23: Bode phase angle and amplitude plots for the corrosion of AZ31 alloy in 0.1 M NaCl medium containing different concentrations of DB at 50 °C.

Fig. 3.24: Bode phase angle and amplitude plots for the corrosion of AZ31 alloy in 0.1 M Na₂SO₄ medium containing different concentrations of DB at 50 °C.

3.3.3 Effect of temperature

Studying corrosion at various intervals of temperature facilitates the assessment of important activation parameters. At any particular DB

concentration, the efficiency of the studied DB declines with the increase in solution temperature, as seen from the results listed in Table 3.31 and Table 3.32. This is a distinguishing trait of physisorbed inhibitors, which desorb at higher temperatures (Bentiss et al. 2005). Arrhenius plots for the corrosion of AZ31 alloy specimen in 0.1 M NaCl and 0.1 M Na₂SO₄ having different amounts of DB are presented in Fig. 3.25.

Fig. 3.25: Arrhenius plot for the corrosion of AZ31 magnesium alloy in a) 0.1 M NaCl and b) 0.1 M Na₂SO₄ media in the presence of different concentrations of DB.

Fig. 3.26: The plots of $\ln(v_{corr}/T)$ vs $(1/T)$ for the corrosion of AZ31 magnesium alloy in a) 0.1 M NaCl and b) 0.1 M Na₂SO₄ media in the presence of different concentrations of DB.

The plots of $\ln(v_{\text{corr}}/T)$ versus $1/T$ for the corrosion of AZ31 magnesium alloy in the presence of different concentrations of DB compound in 0.1 M NaCl and 0.1 M Na₂SO₄ are shown in Fig. 3.26. The activation parameters calculated are summarized in Tables 3.31 and 3.32.

From the data in Table 3.31 and Table 3.32, the following inferences can be drawn. The values of E_a for each DB containing system are greater than E_a of the blank and it gradually increases with the increase in the concentration of DB. E_a is synonymous with the energy barrier for the occurrence of metal corrosion (Schorr and Yahalom 1972). Thus, the presence of DB energetically hinders AZ31 corrosion, most likely by adsorption of the surface film.

The variation of $\Delta H^\#$ is similar to that of E_a and the negative values of $\Delta S^\#$ suggest the formation of the activated complex involves association with the reduction in the randomness of the system.

3.3.4 Adsorption isotherms

An adsorption isotherm is a graphical representation of variation of extent of adsorption with pressure or concentration of on adsorbate at a given constant temperature. The phenomenon of adsorption plays a vital role during the action of corrosion inhibitors. Hence a thorough knowledge about the adsorption isotherm is a prerequisite in understanding the nature of interactions prevailing between the inhibitor molecules and the metal surface. A metal/electrolyte interface has water molecules adsorbed all along. During inhibitor adsorption, the inhibitor molecules in solution ($\text{Inh}_{(\text{sol})}$) replace the previously adsorbed water molecules ($\text{H}_2\text{O}_{(\text{ads})}$) through a process similar to substitution (Tao et al. 2009), as shown below:

where χ is the size ratio corresponding to the number of water molecules replaced upon the adsorption of one inhibitor molecule. χ is specific for an individual inhibitor and is fairly independent of the surface charge on the metal.

Generally, the degree of inhibition brought about by interfacial inhibitors varies as a function of surface coverage (θ). It was attempted to obtain a linear relationship between the values of θ and the concentration of the inhibitor in the solution (C_{inh}) by graphically fitting the parameters to various adsorption isotherms like Langmuir, Temkin, Frumkin, and Flory–Huggins isotherms. The correlation coefficients (R^2) were compared (Wang et al. 2010b). The best fit, however, was achieved with the Langmuir adsorption isotherm, mathematically represented as shown below:

$$\frac{C_{inh}}{\theta} = C_{inh} + \left(\frac{1}{K}\right) \quad (3.13)$$

where K is the equilibrium constant for the adsorption-desorption process. Straight lines were obtained on plotting (C_{inh}/θ) versus C_{inh} at all temperatures. Fig. 3.27 represents the Langmuir adsorption isotherms for the adsorption of DB in 0.1 M of NaCl and 0.1 M Na₂SO₄. K was evaluated as the reciprocal of intercept values obtained from the plots. The values of K were substituted in the reaction isotherm equation below to obtain the standard free energy of adsorption.

$$\Delta G^{\circ}_{ads} = -RT \ln(55.5XK) \quad (3.14)$$

where 55.5 in mol dm³ is the molar concentration of water in the solution, R is the universal gas constant and T is the absolute temperature. The standard enthalpy of adsorption ΔH°_{ads} and standard entropy of adsorption ΔS°_{ads} were calculated from the plot of ΔG°_{ads} versus T , by means of thermodynamic relation below:

$$\Delta G^{\circ}_{ads} = \Delta H^{\circ}_{ads} - T\Delta S^{\circ}_{ads} \quad (3.15)$$

Tables 3.33 and 3.34 enlist all the calculated thermodynamic parameters for the adsorption of DB on the alloy surface in NaCl and Na₂SO₄. The plots though linear with an average linear regression coefficient (R^2) equal to 0.95, deviate slightly from the ideal Langmuir isotherm, in terms that the slopes are close but not equal to unity. This deviation arises as a consequence of mutual interactions among the adsorbed DB. Such intermolecular interactions among

the adsorbate are forbidden as per the assumptions considered for the statistical derivation of the Langmuir equation (Ayawei et al. 2017). The ΔG°_{ads} values are negative and fall within the range -27 kJ mol^{-1} to -31 kJ mol^{-1} . Generally accepted free energy threshold for physisorption and chemisorption, respectively is -20 kJ mol^{-1} and -40 kJ mol^{-1} . The values obtained in the current study are intermediate hinting that the DB adsorb both physically and chemically. The fact that both ΔG°_{ads} and inhibition efficiency decrease with the increase in temperature, indicates that the adsorption of DB on the AZ31 alloy surface in NaCl and Na₂SO₄ are not favoured at high temperature and hence can be considered to be predominantly physisorption. The standard adsorption entropy value is negative; indicating that decrease in disordering takes place on going from the reactant to the alloy adsorbed species. This can be attributed to the fact that adsorption is always accompanied by decrease in entropy (Fawzy et al. 2018).

Fig. 3.27: Langmuir adsorption isotherms for the adsorption of DB on AZ31 alloy in a) 0.1 M NaCl medium and b) 0.1 M Na₂SO₄ medium.

3.3.5 Mechanism of corrosion inhibition

Magnesium dissolution in wet environments generally proceeds by an electrochemical reaction with water to produce magnesium hydroxide and molecular hydrogen (H₂), thus magnesium corrosion is relatively insensitive to oxygen concentration.

Generally, the inhibition brought about by chemical inhibitors is attributed to adsorption and barrier film formation at the metal surface. The DB is an anionic surfactant with the carboxylate polar head and long alkyl hydrophobic tail. The DB might physically adsorb through the electrostatic interactions between their anionic head and Mg^{2+} ions trapped within the imperfections of surface film developed over the α -Mg matrix. There certainly is scope for chemisorption as well, at the cathodic phases which are rich in Mn and Zn elements (Zeng et al. 2014); (Hu et al. 2015). Strong covalent bonds might develop from donor–accepter interactions between unshared electron pairs of oxygen in the inhibitor and vacant d-orbitals of Mn or Zn metal atoms, leading to chemisorption of inhibitors. The DB, chemisorbed along cathodic intermetallic phases are likely to inhibit cathodic hydrogen evolution by blocking the active cathodic reaction sites. The physisorbed surfactant, on the other hand, might precipitate as their sparingly soluble magnesium salts within the pores of the film over the α -Mg matrix. The precipitation is favored due to the very low solubility product of magnesium salt of the surfactant and the presence of sufficiently high amounts of dissolved Mg^{2+} ions. The precipitates fill up the pores and densify the surface film. As an overall result, the electrolyte ingress is reduced on the addition of the surfactant. In all likelihood, van der Waals interactions exist between the long alkyl chains of adsorbed surfactant molecules, which causes the adsorption behavior to slightly deviate from the ideal Langmuir behavior. Such mutual interactions further improve the compactness of the modified film. As an added advantage, the modified film even attains certain hydrophobicity which repels the aqueous corrosive solution (Bentiss et al. 2005).

3.3.6 Surface morphology

Fig. 3.28 and Fig. 3.29 present the SEM images and EDX spectra of the AZ31 magnesium alloy surface after the immersion in 0.1 M NaCl and 0.1 M Na_2SO_4 for 3 h at 30 °C, in the presence of DB, respectively. It is noted that the deterioration of the alloy substrate is suppressed in the presence of DB in the NaCl and Na_2SO_4 . In the presence of DB inhibitor, the AZ31 alloy is less corroded. The surface observed after the addition of DB inhibitor seems to be

more compact and contains fewer cracks in it, supposedly conveying the suppressed corrosion rate. The elements present on the surface of the alloy were ascertained by using the EDX spectra for both when the inhibitor is present in NaCl and Na₂SO₄.

Fig. 3.28: The SEM image and EDX spectrum of AZ31 Mg alloy surface immersed in 0.1 M NaCl medium in the presence of 0.001 M DB for 3 h.

Fig. 3.29: SEM images and EDX spectrum of AZ31 Mg alloy surface immersed in 0.1 M Na₂SO₄ medium in the presence of 0.001 M DB for 3 h.

3.3.7 XPS

Fig. 3.30 and 3.31 shows the XPS survey spectra of AZ31 alloy immersed in 0.01 M NaCl and 0.01 M Na₂SO₄ solution in the presence of DB, respectively. The AZ31 alloy surface consists majorly of Mg, Al, C, O, and N elements in them. Figures 3.32 and 3.33 show the corresponding high-resolution

scans for different elements present on the AZ31 alloy surface. The surface of the alloy has high concentrations of O, C, and N, smaller quantities of Al and Mg. The Mg 1s peak was deconvoluted into three peaks corresponding to $\text{Mg}(\text{OH})_2$, MgO, and MgAl_2O_4 at binding energies 1302.70 eV, 1303.90 eV, and 1304 eV, respectively. The peak associated with Al 2p at ~75 eV is related to MgAl_2O_4 . The O 1s peak corresponds to MgO at 532.10 eV. C 1s is deconvoluted to give a peak at 284.55 eV which is associated with C-C and C-H of the inhibitor molecule. N 1s peak at 398 eV is related to the N-CH₂ bond in the DB inhibitor. The obtained results show that the surfactant molecules have been adsorbed on the surface of the alloy forming a layer on the surface.

Fig. 3.30: XPS spectra of AZ31 Mg alloy surface immersed in 0.2 M NaCl medium in the presence of 0.001 M DB for 3 h at 30 °C.

Fig. 3.31: XPS spectra of AZ31 Mg alloy surface immersed in 0.2 M Na_2SO_4 medium in the presence of 0.001 M DB for 3 h at 30 °C.

Fig. 3.32: XPS spectra (Mg 2s, Al 2p, C 1s, O 1s and, N 1s) of AZ31 Mg alloy immersed in 0.20 M NaCl medium in the presence of 0.001 M DB for 3 h at 30 °C.

Fig. 3.33: XPS spectra (Mg 2s, Al 2p, C 1s, O 1s and, N 1s) of AZ31 Mg alloy immersed in 0.2 M Na₂SO₄ medium in the presence of 0.001 M DB for 3 h at 30 °C.

3.3.8 DFT

As a consequence of using quantum mechanical methods in theoretical calculations, it is necessary to validate the theoretical approach by comparing experimental data (Liu et al. 2018). The optimized structure for the inhibitor, DB, was obtained using DFT calculations at the B3LYP hybrid functional model with def-TZVP basis set and presented in Fig. 3.34. The energy of the highest occupied molecular orbital (E_{HOMO}), the energy of the lowest unoccupied molecular orbital (E_{LUMO}), energy gap (ΔE), hardness (η), softness (σ), ionization potential (IP), electron affinity (EA), electronegativity (χ), and dipole moment (μ) associated with the corrosion-inhibiting ability of DB (Ćurković et al. 2013)(Kaczerewska et al. 2019)(Gad et al. 2018)(Mejeha et al. 2012)(Lukovits et al. 2001)(Farhat A. Ansari 2010) have been evaluated using DFT. The above-mentioned parameters are presented in Table 3.35.

The structure of the molecule is optimized and the negative value of the total energy (-16.87 KeV) indicates a thermodynamically stable molecule. The E_{HOMO} indicates the ability of the inhibitor molecule to contribute electron pairs.

E_{LUMO} is a measure of electron-accepting ability of the inhibitor. E_{HOMO} value of -1.04 eV for the inhibitor DB, indicates the physical adsorption is the basis for the corrosion inhibition action (Pakiet et al. 2019). The low bandgap energy indicates a higher reactivity of the inhibitor molecules, leading to their ready adsorption on AZ31 alloy surface (H. A. Videla; M. F. L. de Mele; G. Brankevich 1988)(Williams et al. 2013)(Liu et al. 2018). The dipole moment value is the measure of the extent of interaction between charged DB molecules and the charged metal surface. The high value of the dipole moment implies a stronger interaction of DB molecules and the AZ31 alloy surface.

The resistance of the inhibitor to charge transfer and its readiness to receive electrons is indicated by its chemical hardness and softness respectively. The strong tendency of DB to attract electrons from metal shows a higher electronegativity value, which in turn indicates the higher ability to act as a corrosion inhibitor.

Fig. 3. 34: Optimized structure and the frontier molecular orbital density distribution of the DB molecule.

3.3.9 Summary

- The effect of anionic Gemini surfactant-based inhibitor on the corrosion of AZ31 Mg alloy in NaCl and Na₂SO₄ solutions were investigated.
- The anionic Gemini surfactant DB was successfully synthesized using EDTA and dibutylamine.
- DB effectively inhibits the corrosion of AZ31 alloy in NaCl and Na₂SO₄ solutions.
- As the concentration of inhibitor is increased, the inhibition efficiency increases, and as the temperature increases, the inhibition efficiency decreases.
- The inhibitor appears to be a mixed-type inhibitor and obeys Langmuir adsorption isotherm.
- The inhibitor reacts with Mg²⁺ ions to form the magnesium salt of the inhibitor on the surface of AZ31 alloy to impart corrosion resistance.

Softness (eV ⁻¹)	0.51

3.4 SODIUM 2,2'-(7,16-DIHEXYL-8,15-DIOXO-7,10,13,16-TETRAAZADOCOSANE-10,13-DIYL)DIACETATE (DH) AS CORROSION INHIBITOR ON AZ31 MAGNESIUM ALLOY IN SODIUM CHLORIDE AND SODIUM SULFATE SOLUTIONS

3.4.1 Potentiodynamic polarization measurements

The potentiodynamic polarization plots for the corrosion of AZ31 magnesium alloy in 0.1 M sodium chloride solution and 0.1 M sodium sulfate solution in the presence of different concentrations of DH, at 50 °C are shown in Fig. 3.35. Similar plots were obtained at other temperatures and also in the other five concentrations each of sodium chloride and sodium sulfate at the different temperatures studied. The potentiodynamic polarization parameters such as corrosion potential (E_{corr}), corrosion current density (i_{corr}), cathodic Tafel slopes (β_c) were calculated from the Tafel plots in the presence of different concentrations of DH at different temperatures and media concentrations are summarized in Tables 3.36 to 3.45. As seen from the data, the presence of inhibitor brings down the corrosion rate considerably. Polarization curves are shifted to a lower current density region indicating a decrease in corrosion rate (Peberé et al. 1990). Inhibition efficiency increases with the increase in the concentration of DH in the corrosion medium.

Fig. 3.35: Potentiodynamic polarization curves for the corrosion of AZ31 alloy in the presence of different concentrations of DH in a) 0.1 M NaCl solution and b) 0.1 M Na₂SO₄ solution at 50 °C.

No definite trend is observed in the shift of E_{corr} values; both anodic and cathodic polarization profiles are influenced simultaneously, almost to the same

extent, which indicates the influence of DH compound on both the anodic and the cathodic reactions; metal dissolution and hydrogen evolution, respectively. The formation of magnesium salt precipitate on the surface, results in the formation of a film on the alloy surface, blocking both anodic and cathodic sites from the corrosive, rendering the inhibition effect on the corrosion of the alloy (Fuchs-Godec 2009). The data in Tables from 3.36 to 3.45 show that there is no significant change in the values of cathodic Tafel slope β_c with the increase in the concentration of the inhibitor. This suggests that the reduction mechanism at the cathode and the oxidation mechanism at the anode are not affected by the presence of inhibitor and hence the corrosion reaction is slowed down by the surface-blocking effect of the inhibitor (Liu et al. 2019). Thus, the inhibitor, DH, can be regarded as a mixed-type inhibitor.

3.4.2 Electrochemical impedance spectroscopy

Nyquist plots for the corrosion of AZ31 magnesium alloy in 0.1 M NaCl solution and 0.1 M Na₂SO₄ solution in the presence of different concentrations of DH are shown in Fig. 3.36. Similar plots were obtained in other concentrations and also at other temperatures.

The shape of the impedance plots for the alloy in the presence of the inhibitor is quite similar to that in the absence of the inhibitor (Montemor and Ferreira 2007). The presence of the inhibitor only increases the impedance without changing other aspects of the behavior. These results are in agreement with the results of polarization measurements that the inhibitor does not alter the mechanism of electrochemical reactions responsible for corrosion. The Nyquist plots display two capacitive semicircles at higher and medium frequencies, former being much similar to the one explained in section 3.3.2. The electrical equivalent circuit presented in Fig. 3.3 was fitted into the impedance data and the electrochemical impedance parameters were calculated. The experimental results of EIS measurements are summarized in Tables 3.46 to 3.55.

The Bode plots of phase angle and amplitude for the corrosion of the AZ31 alloy immersed in 0.1 M NaCl solution and Na₂SO₄ solution at 50 °C in the presence of varying amounts of DH, are shown in Fig. 3.37 and Fig. 3.38,

respectively. As seen from the Bode plots, both the impedance modulus (Z_{mod}) at low frequency and the phase maximum (θ_{max}) at intermediate frequency increase with the increase in DH concentration, which collectively indicates that the presence of highly protective surface film protecting the alloy surface.

Fig. 3.36: Nyquist plots for the corrosion of AZ31 alloy in the presence of different concentrations of DH in a) 0.1 M NaCl and b) 0.1 M Na₂SO₄ at 50 °C.

Fig. 3.37: Bode phase angle and amplitude plots for the corrosion of AZ31 alloy in 0.1 M NaCl medium containing different concentrations of DH at 50 °C.

Fig. 3.38: Bode phase angle and amplitude plots for the corrosion of the AZ31 alloy in 0.1 M Na₂SO₄ medium containing different concentrations of DH at 50 °C.

3.4.3 Effect of temperature

The results in Tables 3.36 and 3.45 show that corrosion rate increases and the inhibition efficiency of DH decrease with the increase in temperature. The decrease in inhibition efficiency with the increase in temperature indicates desorption of the inhibitor molecules from the metal surface on increasing the temperature. This fact is also suggestive of physisorption of the inhibitor molecules on the metal surface.

The Arrhenius plots for the corrosion of AZ31 magnesium alloy in the presence of different concentrations of DH in 0.1 M NaCl solution and Na₂SO₄ solution are shown in Fig. 3.39. The plots of $\ln(v_{\text{corr}}/T)$ versus $1/T$ in 0.1 M NaCl solution and Na₂SO₄ solution in the presence of various concentrations of DH are shown in Fig. 3.40. The calculated values of E_a , ΔH^\ddagger , and ΔS^\ddagger are given in Tables 3.56 and 3.57. The proportionate increase in the activation energy on the addition of DH can be attributed to the adsorption of DH providing a barrier on the alloy surface.

The values of entropy of activation indicate that the activated complex in the rate-determining step represents an association rather than dissociation,

resulting in a decrease in randomness on going from the reactants to the activated complex.

Fig. 3.39: Arrhenius plots for the corrosion of AZ31 magnesium alloy in a) 0.1 M NaCl and b) 0.1 M Na $_2$ SO $_4$ in the presence of different concentrations of DH.

Fig. 3.40: The plots of $\ln(v_{\text{corr}}/T)$ versus $1/T$ for the corrosion of AZ31 magnesium alloy in a) 0.1 M NaCl and b) 0.1 M Na $_2$ SO $_4$ in the presence of different concentrations of DH.

3.4.4 Adsorption isotherms

The adsorption of DH on the surface of AZ31 magnesium alloy was found to obey Langmuir adsorption isotherm. The Langmuir adsorption

isotherms for the adsorption of DH on AZ31 magnesium alloy in 0.1 M NaCl solution and Na₂SO₄ solution are shown in Fig. 3.41.

The thermodynamic data obtained for the adsorption of DH on AZ31 magnesium alloy are tabulated in Tables 3.58 and 3.59. The linear regression coefficients are close to unity and the slopes of the straight lines are nearly unity, suggesting that the adsorption of DH obeys Langmuir's adsorption isotherm with negligible interaction between the adsorbed molecules. The free energy values suggest that the DH undergoes both physisorption and chemisorption. η (%) reduces with the increase in temperature, which is characteristic of physisorbed inhibitors. Both these results hint at the predominance of physisorption over chemisorption.

Fig. 3.41: Langmuir's adsorption isotherms for the adsorption of DH on AZ31 magnesium alloy in a) 0.1 M NaCl medium and b) 0.1 M Na₂SO₄ medium.

3.4.5 Mechanism of corrosion inhibition

The corrosion inhibition mechanism of DH in sodium sulfate solution can be explained in the same lines as that of DB in the previous section. The inhibitor DH protects the alloy surface through the predominant physisorption mode in which the DH gets adsorbed on the alloy surface through electrostatic attraction.

3.4.6 SEM

Fig. 3.42 presents the SEM image and EDX spectrum of the AZ31 magnesium alloy surface after the immersion in 0.2 M NaCl in the presence of DH for 3 h at 30 °C. Figure 3.43 presents the SEM image and EDX spectrum of AZ31 magnesium alloy surface after the immersion in 0.2 M Na₂SO₄ in the presence of DH for 3 h at 30 °C. It is noted that the deterioration of the alloy substrate is suppressed in the presence of DH in the NaCl and Na₂SO₄ media as compared with the SEM image of alloy samples immersed in the corrosion media in the absence of the inhibitor presented in Fig. 3.10 and Fig. 3.12. The SEM image in Fig. 3.42 and Fig. 3.43 show a more compact surface and contain fewer cracks in it. The elements present on the surface of the alloy were ascertained by using the EDX spectra of the alloy sample.

Fig. 3.42: SEM image and EDX spectra of the AZ31 magnesium alloy surface after the immersion in 0.2 M NaCl in the presence of DH for 3 h at 30 °C.

Fig. 3.43: SEM image and EDX spectra of the AZ31 magnesium alloy surface after the immersion in 0.2 M Na₂SO₄ in the presence of DH for 3 h at 30 °C.

3.4.7 XPS

Fig. 3.44 and Fig. 3.45 present the XPS survey spectra of the corroded AZ31 magnesium alloy in the corrosion medium of 0.2 M NaCl and 0.2 M Na₂SO₄ containing 0.001 M DH inhibitor. Fig. 3.46 and Fig. 3.47 show the corresponding individual XPS spectra of Mg (2s), Al (2p), C (1s), O (1s) and, N (1s) in NaCl and Na₂SO₄. The Mg (2s) peak was deconvoluted to three peaks corresponding to Mg(OH)₂, MgCO₃, and MgO at 88 eV, 88.9 eV, and 89.4 eV, respectively. The C (1s) peak was deconvoluted into three peaks at 284 eV, 286 eV, and 288 eV corresponding to C-C/ C-H bonds, C-N bonds, and COO⁻ group, respectively (Gece 2008). The O (1s) peak was deconvoluted into two peaks at 532 eV and 534 eV, corresponding to O of C=O, MgO, and Mg(OH)₂, respectively (Gao and Liang 2007). The N (1s) peak shows only one peak corresponding to the presence of N as N-CH₂ at ~399 eV. The Al (2p) peak indicates the presence of Al as MgAl₂O₄. The above facts indicate the surfactant molecules to be present on the alloy surface and support the proposal that the alloy surface is protected from corrosion through the formation of a protective film by the DH molecules.

Fig. 3.44: The XPS survey spectra of the corroded AZ31 magnesium alloy immersed in the corrosion medium of 0.2 M NaCl containing 0.001 M of DH for 3 h at 30 °C.

Fig. 3.45: The XPS survey spectra of the corroded AZ31 magnesium alloy immersed in the corrosion medium of 0.2 M Na₂SO₄ containing 0.001 M of DH for 3 h at 30 °C.

Fig. 3.46: XPS spectra (Mg 1s, Al 2p, C 1s, O 1s and, N 1s) of AZ31 Mg alloy immersed in 0.2 M NaCl medium in the presence of 0.001 M DH for 3 h at 30 °C.

Fig. 3.47: XPS spectra (Mg 1s, Al 2p, C 1s, O 1s and, N 1s) of AZ31 Mg alloy immersed in 0.2 M Na₂SO₄ medium in the presence of 0.001 M DH for 3 hours at 30 °C.

3.4.8 DFT

The optimized structure for the inhibitor, DH, was obtained using DFT calculations at the B3LYP hybrid functional model with def-TZVP basis set and presented in Figure 3.48. The energy of the highest occupied molecular orbital (E_{HOMO}), the energy of the lowest unoccupied molecular orbital (E_{LUMO}), energy gap (ΔE), hardness (η), softness (σ), ionization potential (I_p), electron affinity (EA), electronegativity (χ), and dipole moment (μ) associated with the corrosion-inhibiting ability of DH have been evaluated using DFT. The above-mentioned parameters are presented in Table 3.60.

The structure of the molecule was optimized and a negative value of the total energy (-2.32 keV) indicates a thermodynamically stable molecule. E_{HOMO} value of -1.01 eV for the inhibitor DH, indicates the physical adsorption. The donation of electrons results in chemical adsorption, the negative value of E_{HOMO} indicates physisorption rather than chemisorption (Vengatesh and Sundaravadivelu 2019). The low bandgap energy suggests a higher reactivity of the inhibitor molecules, leading to their ready adsorption on the AZ31 alloy surface. The dipole moment value is the measure of the extent of interaction between charged DH molecules and the charged metal surface. The high value of the dipole moment implies a stronger interaction between DH molecules and the AZ31 alloy surface.

The resistance of the inhibitor to charge transfer and its readiness to receive electrons is indicated by its chemical hardness and softness respectively. The strong tendency of diacetate group to attract electrons from metal shows a higher electronegativity value, which in turn indicates the higher ability of DH to act as a corrosion inhibitor.

Fig. 3.48: Optimized structure and the frontier molecular orbital density distribution of the DH molecule.

3.4.9 Summary

Anionic Gemini surfactant based on EDTA derivatives, DH, was synthesized and used as corrosion inhibitor on AZ31 Mg alloy in different concentrations of NaCl solution and Na₂SO₄ solution. The surfactant DH acted as a mixed type of inhibitor and the inhibitor efficiency increased with the increase in the concentration of DH and decreased with the rise in temperature and the increase in the concentration of NaCl and Na₂SO₄ in the medium. The surfactant was adsorbed predominantly through physisorption and obeyed Langmuir adsorption isotherm. The quantum chemical calculations supported the experimental observations.

3.5.1 Potentiodynamic polarization measurements

Potentiodynamic polarization plots for the corrosion of AZ31 Mg alloy in 0.1 M NaCl solution and 0.1 M Na₂SO₄ solution in the presence of varying concentrations of DO compound at 50 °C is shown in Fig. 3.49. Similar plots were obtained at other temperatures also. The corrosion current density (i_{corr}) values were obtained by the extrapolation of cathodic branches of the polarization plots. The polarization curves are shifted to a lower current density region as the concentration of DO increases, which reflects the corrosion inhibition produced by DO. But there is no significant change in the shape of the Tafel branches, indicating that DO did not alter the corrosion mechanism. DO might have played an important role by blocking the active sites of reaction on the metal surface, likely to be by adsorption.

Tables 3.61 to 3.70 summarize the potentiodynamic polarization parameters like corrosion potential (E_{corr}), corrosion current density (i_{corr}), and cathodic slope (β_c), corrosion rate (v_{corr}), and inhibition efficiency (η) in NaCl and Na₂SO₄ media.

From Tables 3.61 to 3.70 it is observed that the inhibition efficiency increases with the increase in the concentration of DO up to an optimum concentration of 1.5 mmol dm⁻³, and above which the increase in inhibition is negligible. Efficient surface coverage could be credited to the increase in inhibition efficiency. Thus, 1.5 mmol dm⁻³ of DO could be attributed as the most optimum and economic concentration of the surfactant for inhibiting AZ31 Mg alloy, at the presented conditions. The results show that there are no significant changes in the E_{corr} values on the addition of the surfactant, indicating that DO inhibits both the anodic and cathodic reactions as a mixed inhibitor, presumably by covering both the anodic and cathodic sites on the alloy surface.

Fig. 3.49: Potentiodynamic polarization curves for the corrosion of AZ31 alloy in the presence of different concentrations of DO in a) 0.1 M NaCl solution and b) 0.1 M Na₂SO₄ solution at 50 °C.

3.5.2 Electrochemical impedance spectroscopy

The Nyquist plots for the corrosion of alloy in 0.1 M NaCl medium and 0.1 M Na₂SO₄ medium at 50 °C with varying concentrations of DO are presented in Fig. 3.50. The Nyquist plots are similar to the ones in the previous sections. As shown in Fig. 3.50, there is an increase in the size of the capacitance loop with the increase in the concentration of DO with no change in its shape compared with the blank solution, which implies that DO consistently reduces the corrosion rate without changing the corrosion mechanism.

Fig. 3.50: Nyquist plots for the corrosion of AZ31 alloy in the presence of different concentrations of DO in a) 0.1 M NaCl solution and b) 0.1 M Na₂SO₄ solution at 50 °C.

The impedance parameters (R_{hf} , C_{dl} , R_f , R_{dif} , C_f) deduced from impedance measurements are tabulated in Tables 3.71 to 3.80 in NaCl and Na₂SO₄ solutions of different concentrations, in the presence of different concentrations of DO at different temperatures.

The Bode plots of phase angle and amplitude for the corrosion of the AZ31 Mg alloy immersed in 0.1 M NaCl solution and 0.1 M Na₂SO₄ solution at 50 °C, respectively, are shown in Fig. 3.51 and Fig. 3.52. As seen from the Bode plots, both the impedance modulus (Z_{mod}) at low frequency and the phase maximum (θ_{max}) at intermediate frequency increase with the increase in DO concentration, which collectively indicates the progressive formation of protective surface film by the inhibitor, protecting the alloy surface.

Fig. 3.51: Bode phase angle and amplitude plots for the corrosion of the AZ31 alloy in 0.1 M NaCl medium containing different concentrations of DO at 50 °C.

Fig. 3.52: Bode phase angle and amplitude plots for the corrosion of the AZ31 alloy in 0.1 M Na₂SO₄ medium containing different concentrations of DO at 50 °C.

3.5.3 Effect of temperature

The data presented in the previously mentioned tables show a steady decrease in the inhibition efficiency as the temperature increases, indicating the possible physisorption of the inhibitor molecules on the alloy surface. Fig. 3.53 shows the Arrhenius plots for the corrosion of AZ31 Mg alloy in 0.1 M NaCl and 0.1 M Na₂SO₄ containing different concentrations of DO. The average linear regression coefficient (R^2) of 0.95 was obtained.

Fig. 3.53: Arrhenius plots for the corrosion of AZ31 magnesium alloy in a) 0.1 M NaCl and b) 0.1 M Na₂SO₄ media in the presence of different concentrations of DO.

Fig. 3.54 represents the plots of $\ln(v_{\text{corr}}/T)$ versus $(1/T)$ for the corrosion of AZ31 Mg alloy in 0.1 M NaCl and Na₂SO₄ containing varying concentrations of DO inhibitor. Calculated data of ΔH^\ddagger , ΔS^\ddagger , E_a , are tabulated in Tables 3.81 and 3.82. As observed from the data in Tables 3.81 and 3.82, E_a values increase with the increase in the concentration of inhibitor, which indicates the increased energy barrier for the occurrence of corrosion, because of the increase in surface coverage brought by the inhibitor (Lamaka et al. 2007). ΔS^\ddagger in both blank and DO containing systems show large negative values which show that the activated complex in the rate-determining step represents association rather than dissociation. This indicates that there is a decrease in randomness when the activated complex is formed from the reactants of corrosion reaction (Heakal et al. 2012, Frignani et al. 2012).

Fig. 3.54: The plots of $\ln(v_{\text{corr}}/T)$ versus $1/T$ for the corrosion of AZ31 magnesium alloy in a) 0.1 M NaCl and b) 0.1 M Na₂SO₄ in the presence of different concentrations of DO.

3.5.4 Adsorption isotherms

The Langmuir adsorption isotherms for the adsorption of DO compound on AZ31 Mg alloy surface at different temperatures in 0.1 M NaCl and 0.1 M Na₂SO₄ are presented in Fig. 3.55. The graph exhibited linear behavior, but the slopes are not equal to one. The average linear regression coefficient (R^2) of 0.95 was obtained. This deviation from ideal Langmuir behavior can be attributed to interactions among the adsorbed species (Frignani et al. 2012).

The thermodynamic parameters for the adsorption of DO on the AZ31 Mg alloy surface in NaCl and Na₂SO₄ media are tabulated in Tables 3.83 and 3.84. The negative values of ΔG°_{ads} indicate that the process of adsorption of DO is spontaneous and an adsorbed film on the alloy surface is stable. The free energy values suggest that the DO undergoes both physisorption and chemisorption. The fact that both ΔG°_{ads} and inhibition efficiency decrease with the increase in temperature indicates that the adsorption of the inhibitor on the AZ31 alloy surface in NaCl and Na₂SO₄ media is not favored at high temperature and hence can be considered to be predominantly physisorption. The standard entropy of adsorption value is negative; indicating that a decrease in disordering takes place when the inhibitor species gets adsorbed on the alloy surface.

Fig. 3.55: Langmuir adsorption isotherm for the adsorption of DO on AZ31 magnesium alloy in a) 0.1 M NaCl medium and b) 0.1 M Na₂SO₄ medium.

3.5.5 SEM

Fig. 3.56 and Fig. 3.57 present the SEM images and EDX spectra of the alloy surface immersed in 0.1 M NaCl solution and 0.1 M Na₂SO₄ solution, respectively. It can be seen from SEM images in Fig. 3.8 (section 3.1), Fig. 3.56, and Fig. 3.57 that the surface of the AZ31 alloy is less deteriorated in the presence of the inhibitor. EDX spectra in the presence of inhibitor show that the surface contains intense peaks of carbon, nitrogen, and oxygen along with Mg,

Al, and other alloying elements, indicating the DO surfactant on the surface of the alloy.

Fig. 3.56: SEM image and EDX spectrum of the AZ31 magnesium alloy surface after immersion in 0.1 M NaCl in the presence of DO for 3 h at 30 °C.

Fig. 3.57: SEM image and EDX spectrum of the AZ31 magnesium alloy surface after immersion in 0.1 M Na₂SO₄ in the presence of DO for 3 h at 30 °C.

3.5.6 XPS

Fig. 3.58 and Fig. 3.59 show the XPS survey spectra and individual spectra of elements of AZ31 magnesium alloy immersed in 0.1 M NaCl and 0.1 M Na₂SO₄, respectively. The high-resolution Mg 2s spectrum for magnesium

alloys in the absence of inhibitor displays three peaks at 88.8 eV, 87.3 eV, and 89.2 eV. It is attributed to MgO, Mg(OH)₂, and Mg, respectively (Gece 2008). The MgO and Mg(OH)₂ are the main components of the alloy with the larger peak area indicating the corrosion. The Mg 1s spectrum for Mg AZ31 alloy immersed in anionic Gemini surfactant also has three peaks corresponding to the same products, MgO, Mg(OH)₂, and Mg, except that the peak area is varied. The corrosion is retarded since the peak area of Mg is larger than that of other corrosion products.

In the presence of inhibitors, O 1s gave a peak of Mg(OH)₂ /MgO is kept at 531.1 eV [47 Zhang 2020]. The appearance of C 1s deconvoluted peak at 284.8 eV of -C-O and -C=O should be related to the presence of DO, which consists of carboxylate groups on the surface of the alloy. The N 1s spectrum shows a peak at 399.2 eV, which shows the presence of CH₂-N-C=O bond. The XPS results evidently show that the inhibitor is adsorbed on the surface to repel the water molecules and corrosive species.

Fig. 3.58: XPS survey spectra and individual spectra of elements (Mg 1s, Al 2p, C 1s, O 1s and, N 1s) of AZ31 Mg alloy immersed in 0.1 M NaCl medium in the presence of 0.001 M DO for 3 h at 30 °C.

Fig. 3.59: XPS survey spectra and individual spectra of elements (Mg 1s, Al 2p, C 1s, O 1s and, N 1s) of AZ31 Mg alloy immersed in 0.1 M Na_2SO_4 medium in the presence of 0.001 M DO for 3 h at 30 °C.

3.5.7 DFT

The optimized structure for the inhibitor, DO, was obtained using DFT calculations at the B3LYP hybrid functional model with def-TZVP basis set and presented in Fig. 3.60. The calculated parameters are presented in Table 3.85.

The structure of the molecule is optimized and the negative value of the total energy (-2.315 KeV) indicates a thermodynamically stable molecule. E_{HOMO} value indicates the physical adsorption as the basis for the corrosion inhibition action. The low bandgap energy suggests a higher reactivity of the inhibitor molecules, leading to their ready adsorption on AZ31 alloy surface (H. A. Videla; M. F. L. de Mele; G. Brankevich 1988)(Williams et al. 2013)(Liu et al. 2018). The high value of the dipole moment implies a stronger interaction of DO molecules with the AZ31 alloy surface.

The strong tendency of DO to attract electrons from metal shows a higher electronegativity value, which in turn indicates the higher ability of DO to act as a corrosion inhibitor.

Fig. 3.60: Optimized structure and the frontier molecular orbital density distribution of the DO molecule.

3.5.8 Summary

Anionic Gemini surfactant, DO, was synthesized and used as a corrosion inhibitor on AZ31 Mg alloy in different concentrations of NaCl solution and Na₂SO₄ solution. The inhibitor surfactant acted as a mixed type of inhibitor and the inhibitor efficiency increased with the increase in the concentration of DO and decreased with the increase in temperature and the increase in the concentration of NaCl and Na₂SO₄ media. The surfactant was adsorbed predominantly through physisorption and obeyed Langmuir adsorption isotherm. The quantum chemical calculations supported the experimental observations.

3.6 SODIUM 2,2'-(11,20-DIDECYL-12,19-DIOXO-11,14,17,20-TETRAAZATRIACONTANE-14,17-DIYL)DIACETATE (DC) AS CORROSION INHIBITOR FOR AZ31 ALLOY IN SODIUM CHLORIDE AND SODIUM SULFATE SOLUTIONS

3.6.1 Potentiodynamic polarization measurements

Potentiodynamic polarization plots for the corrosion of AZ31 Mg alloy in 0.1 M NaCl and 0.1 M Na₂SO₄ at 50 °C in the presence of varying concentrations of DC are shown in Fig. 3.61. Similar plots were obtained at other temperatures also. The polarization curves are shifted to a lower current density region as the concentration of DC increases, which reflects the corrosion inhibition produced by the inhibitor. But there is no significant change in the shape of the Tafel branches, indicating that DC did not alter the corrosion mechanism. DC might have played an important role by blocking the active sites of reaction on the metal surface, likely to be by adsorption.

Fig. 3. 61: Potentiodynamic polarization curves for the corrosion of AZ31 alloy in the presence of different concentrations of DC in a) 0.1 M NaCl solution and b) 0.1 M Na₂SO₄ solution at 50 °C.

The electrochemical polarization parameters are summarized in Tables 3.86 to 3.95. From Table 3.86 to 3.95, it is observed that in the presence of DC, i_{corr} (corrosion current density) decreases, which shows that corrosion inhibition is achieved upon the addition of DC. The inhibition efficiency increases with the increase in the concentration of DC up to an optimum concentration of 0.001 M, and above which the increase in inhibition efficiency is negligible. Efficient

surface coverage could be credited to the increase in inhibition efficiency. Thus, 0.001 M could be attributed as the most optimum and economic concentration of DC for inhibiting AZ31 Mg alloy, at the presented conditions.

3.6.2 Electrochemical impedance spectroscopy

The Nyquist plots for the corrosion of alloy AZ31 Mg alloy in 0.1 M NaCl and 0.1 M Na₂SO₄ medium at 50 °C in the presence of varying concentrations of DC are represented in Fig. 3.62. The Nyquist plots are similar to the ones discussed in the earlier sections. As shown in Fig. 3.62, there is an increase in the size of capacitance loop with the increase in the concentration of DC with no change in its shape, which implies that DC consistently reduces the corrosion rate without changing the corrosion mechanism. The impedance parameter are summarized in Tables 3.96 to 3.105.

Fig. 3.62: Nyquist plots for the corrosion of AZ31 alloy in a) 0.1 M NaCl and b) 0.1 M Na₂SO₄ in the presence of different concentrations of DC at 50 °C.

It can be seen from Tables 3.96 to 3.105 that the increase in the concentration of DC results in an increase in R_f and R_{dif} and the decrease in both C_{dl} and C_f , which can be possibly due to the decrease in local dielectric constant or increase in the thickness of surface film. R_f on the other hand is the measure of protective performance of surface film, which increases upon the addition of DC.

The Bode plots of phase angle and amplitude for the corrosion of the AZ31 alloy immersed in 0.1 M NaCl and 0.1 M Na₂SO₄ solutions at 50 °C in the presence of varying amounts of DC, are shown in Fig. 3.63 and Fig. 3.64, respectively. As seen from the Bode plots, both the impedance modulus (Z_{mod}) at low frequency and the phase maximum (θ_{max}) at intermediate frequency increase with the increase in DC concentration, which collectively indicates that the presence of highly protective surface film protects the alloy surface.

Fig. 3.63: Bode phase angle and amplitude plots for the corrosion of AZ31 alloy in 0.1 M NaCl medium in the presence of different concentrations of DC at 50 °C.

Fig. 3.64: Bode phase angle and amplitude plots for the corrosion of AZ31 alloy in 0.1 M Na₂SO₄ medium in the presence of different concentrations of DC at 50 °C.

3.6.3 Effect of temperature

The values presented in Tables 3.85 and 3.94 show a steady decrease in inhibition efficiency as the temperature increases, indicating the physisorption of the inhibitor molecules on the alloy surface. On the other hand, it can also be due to the increased solubility of the magnesium - DC precipitate film, causing desorption of the inhibitor layer from the alloy surface (Wang et al. 2010). The Arrhenius plots for the corrosion of AZ31 alloy in 0.1 M NaCl and 0.1 M Na₂SO₄ containing varying concentrations of DC compound are shown in Fig. 3. 65.

Fig. 3.65: Arrhenius plots for the corrosion of AZ31 magnesium alloy in a) 0.1 M NaCl and b) 0.1 M Na₂SO₄ media in the presence of different concentrations of DC.

Fig. 3.66: The plots of $\ln(v_{\text{corr}} / T)$ versus $1/T$ for the corrosion of AZ31 magnesium alloy in a) 0.1 M NaCl and b) 0.1 M Na₂SO₄ in the presence of different concentrations of DC.

Fig. 3. 66 presents the plots of $\ln (v_{\text{corr}}/T)$ versus $(1/T)$ for the corrosion of AZ31 Mg alloy in 0.1 M NaCl and 0.1 M Na₂SO₄ containing varying concentrations of DC. Calculated data of ΔH^\ddagger , ΔS^\ddagger , E_a , are tabulated in Tables 3.106 and 3.107.

As observed from the data in Table 3.106 and 3.107, E_a values increase with the increase in the concentration of DC, which indicates the increased energy barrier for the occurrence of corrosion due to the increase in surface coverage brought by the inhibitor (Ardelean et al. 2008). ΔS^\ddagger in both blank and DC containing systems shows large negative values which show that the activated complex in the rate-determining step represents association rather than dissociation.

3.6.4 Adsorption Behavior

The values of θ at different DC concentrations (C_{inh}) were calculated from the results of polarization studies. The values of θ and C_{inh} were fitted to various adsorption isotherms with an aim to obtain a linear relationship. It was found that Langmuir adsorption isotherm gave best fit results. The Langmuir adsorption isotherms for the adsorption of DC on AZ31 Mg alloy surface in 0.1 M NaCl and 0.1 M Na₂SO₄ at different temperatures are presented in Fig. 3.67. The graph exhibited linear behavior, but the slopes are not equal to one. The average linear regression coefficient (R^2) of 0.95 was obtained. This deviation from ideal Langmuir behavior can be attributed to interactions among the adsorbed species (Baril and Pébère 2001).

The thermodynamic parameters for the adsorption of DC on the AZ31 Mg alloy surface in NaCl and Na₂SO₄ are tabulated in Tables 3.108 and 3.109. The negative values of $\Delta G^\circ_{\text{ads}}$ indicate that the process of adsorption of DC is spontaneous and an adsorbed film on the alloy surface is stable. The values obtained for $\Delta G^\circ_{\text{ads}}$ are negative and fall within the range of -28 to -33 kJ mol⁻¹, indicating the adsorption of the inhibitor molecules are by both physical and chemical processes. The fact that both $\Delta G^\circ_{\text{ads}}$ and inhibition efficiency decrease with the increase in temperature indicates that the adsorption of the inhibitor on

the AZ31 alloy surface in NaCl and Na₂SO₄ medium is not favored at high temperature and hence can be considered to be predominantly physisorption. The standard adsorption entropy value is negative; indicating that a decrease in disordering takes place when the inhibitor species gets adsorbed on the alloy surface.

Fig. 3.67: Langmuir's adsorption isotherm for the adsorption of DC on AZ31 magnesium alloy in a) 0.1 M NaCl medium and b) 0.1 M Na₂SO₄ medium.

3.6.5 SEM

Fig. 3.68 depicts the SEM image and EDX spectrum of AZ31 Mg alloy surface immersed in 0.1 M NaCl solution in the presence of 0.001 M DC. Fig. 3.69 presents the SEM image and EDX spectrum of AZ31 Mg alloy surface immersed in 0.1 M Na₂SO₄ solution in the presence of 0.001 M DC. In the EDX spectra apart from the peaks of Mg, Al, Zn, and Cl, additional small peaks for carbon, oxygen, and nitrogen are obtained, which indicate the presence of some organic moieties on the alloy surface, possibly the surface adsorbed DC molecules. It is also observed that the intensity of the Mg peak is reduced.

Fig. 3.68: SEM image and EDX spectrum of the AZ31 magnesium alloy surface immersed in 0.1 M NaCl in the presence of DC for 3 h at 30 °C.

Fig. 3.69: SEM image and EDX spectrum of the AZ31 magnesium alloy surface immersed in 0.1 M Na₂SO₄ in the presence of DC for 3 h at 30 °C.

3.6.6 XPS

Fig. 3.70 and Fig. 3.71 show the XPS survey spectra and individual spectrum corresponding to different elements present on the surface of the AZ31 alloy immersed in 0.1 M NaCl and 0.1 M Na₂SO₄ media for 3 h in the presence of 0.001 M DC at 30 °C. The high-resolution Mg 2s spectrum for magnesium alloys immersed in DC inhibitor has peaks assigned to Mg, MgO, and Mg(OH)₂.

Fig. 3.70: XPS survey spectra and individual spectra of elements (Mg 2s, Al 2p, C 1s, O 1s and, N 1s) of AZ31 Mg alloy immersed in 0.1 M NaCl medium in the presence of 0.001 M DC for 3 h at 30 °C.

Fig. 3.71: XPS survey spectra and individual spectra of elements (Mg 2s, Al 2p, C 1s, O 1s and, N 1s) of AZ31 Mg alloy immersed in 0.1 M Na₂SO₄ medium in the presence of 0.001 M DC for 3 h at 30 °C.

The corrosion is retarded since the peak area of Mg is larger than Mg(OH)₂. For the O 1s spectrum, the peak ~531.2 corresponds to MgO. The Al 2p spectra show a broad peak centered at 74.7 eV which indicates the co-existence of aluminum oxide or aluminum hydroxide. The C 1s spectra can be fitted to the presence of C-C/C-H groups at peak 284.8 eV. N 1s spectrum shows a peak at 399.2 eV, which shows the presence of C-N bond. The XPS results show that the inhibitor not only is adsorbed on the surface to repel the water molecules.

3.6.7 DFT

The optimized structure for the inhibitor, DC, was obtained using theoretical calculations using B3LYP hybrid functional model with def-TZVP basis set and presented in Fig. 3. 72. The structure of the molecule is optimized and the negative value of the total energy (-2.629 KeV) predicts a thermodynamically stable molecule. E_{HOMO} value shows the physical adsorption as the basis for corrosion inhibition action. The low bandgap energy shows higher reactivity of the inhibitor molecules, leading to their ready adsorption on AZ31 Mg alloy surface. The high value of the dipole moment implies a stronger interaction of DC molecules with the AZ31 alloy surface. The strong tendency of DC to attract electrons from metal shows a higher electronegativity value, which in turn indicates the higher ability of DC to act as a corrosion inhibitor. The calculated parameters are presented in Table 3.110.

Fig. 3.72: Optimized structure and the frontier molecular orbital density distribution of the DC molecule.

3.6.8 Summary

Anionic Gemini surfactant, DC, was synthesized and used as a corrosion inhibitor on AZ31 Mg alloy in different concentrations of NaCl and Na₂SO₄. The surfactant DC acted as a mixed type of inhibitor and the inhibitor efficiency increased with the increase in the concentration of DC and decreased with the rise in temperature and the increase in the concentration of NaCl and Na₂SO₄ in the medium. The surfactant was adsorbed predominantly through physisorption and obeyed Langmuir adsorption isotherm. The quantum chemical calculation supported the experimental observation.

Table 3.86: Electrochemical polarization parameters for the corrosion of AZ31 alloy in 0.05 M NaCl solution in the presence of DC at different temperatures.

Inhibitor concentration (mmol.dm ⁻³)	Temperature (°C)	E_{corr} vs SCE (mV)	i_{corr} (μA cm ⁻²)	$-\beta_c$ (mV dec ⁻¹)	v_{corr} (mm y ⁻¹)	η (%)

3.7 SODIUM 2,2'-(13,22-DIDODECYL-14,21-DIOXO-11,14,17,20-TETRAAZATETRATRIACONTANE-16,19-DIYL)DIACETATE (DD) AS CORROSION INHIBITOR FOR AZ31 MAGNESIUM ALLOY IN SODIUM CHLORIDE AND SODIUM SULFATE MEDIUM SOLUTIONS

3.7.1 Potentiodynamic polarization measurements

Fig. 3.73 shows the potentiodynamic polarization plots for the corrosion of AZ31 magnesium alloy in 0.1 M NaCl and 0.1 M Na₂SO₄ in the presence of different concentrations of DD at 50 °C.

Tables 3.111 to 3.120 list the electrochemical polarization parameters for the corrosion of AZ31 alloy in NaCl and Na₂SO₄ solutions in the presence of different concentrations of DD at different temperatures. Inhibition efficiency increases remarkably as the amount of inhibitor is increased. The inhibition efficiency increases with the increase in the concentration of DD up to an optimum concentration of 0.0005 M, and above which the increase in inhibition efficiency is negligible. Efficient surface coverage could be credited to the increase in inhibition efficiency.

Fig. 3.73: Potentiodynamic polarization curves for the corrosion of AZ31 alloy in the presence of different concentrations of DD in a) 0.1 M NaCl solution and b) 0.1 M Na₂SO₄ solution at 50 °C.

3.7.2 Electrochemical impedance spectroscopy (EIS) studies

Nyquist plots for the corrosion of AZ31 Mg alloy in 0.1 M NaCl and 0.1 M Na₂SO₄ in the presence of different concentration of DD inhibitor are shown

in Fig. 3.74. The Nyquist plots are similar to the ones obtained in the presence of inhibitors discussed in the previous sections.

The Electrochemical impedance parameters for the corrosion AZ31 Mg alloy in NaCl and Na₂SO₄ media in the presence of different concentrations of DD have been tabulated in Tables 3.121 to 3.130. All the explanation regarding the electrical equivalent circuit is the same as in the earlier sections.

Fig. 3.74: Nyquist plots for the corrosion of AZ31 alloy in a) 0.1 M NaCl and b) 0.1 M Na₂SO₄ in the presence of different concentrations of DD at 50 °C.

Figures 3.75 and 3.76 show the Bode plots for the corrosion of AZ31 Mg alloy in 0.1 M NaCl and 0.1 M Na₂SO₄ media containing varying concentrations of the inhibitors at 50 °C. The plots indicate that the addition of the inhibitors increases the low-frequency impedance modulus (Z_{mod}) and the medium frequency phase angle maximum (θ_{max}). The values of both Z_{mod} and θ_{max} show that the inhibitor shows good inhibition efficiencies.

Fig. 3.75: Bode phase angle and amplitude plots for the corrosion of AZ31 in 0.1 M NaCl medium containing different concentrations of DD at 50 °C.

Fig. 3.76: Bode phase angle and amplitude plots for the corrosion of the AZ31 alloy in 0.1 M Na₂SO₄ medium containing different concentrations of DD at 50 °C.

3.7.3 Effect of temperature on inhibitors

It is seen from Tables 3.111 to 3.120 that the inhibition efficiency of DD decreases with the rise in temperature of the medium. Physical adsorption of the inhibition on the alloy surface is predicted due to the decrease in the inhibition efficiency with the increase in temperature (Antropov 1967).

Arrhenius plots for the corrosion of the AZ31 alloy in 0.1 M NaCl and 0.1 M Na₂SO₄ in the presence of the different concentrations of DD are shown in Figure 3.77.

Figure 3.78 represents the plots of $\ln(v_{corr}/T)$ vs. $(1/T)$ for the corrosion of AZ31 Mg alloy in 0.1 M NaCl and 0.1 M Na₂SO₄ media containing different concentrations of DD. The activation parameters calculated are listed in Tables 3.131 and 3.132. From the tabulated values it is seen that the activation energy (E_a) is higher in the presence of the inhibitor, and it increases with the rise in the concentrations of the inhibitor.

Fig. 3.77: Arrhenius plots for the corrosion of AZ31 magnesium alloy in a) 0.1 M NaCl and b) 0.1 M Na₂SO₄ in the presence of different concentrations of DD.

Fig. 3.78: The plots of $\ln(v_{corr} / T)$ versus $1/T$ for the corrosion of AZ31 magnesium alloy in a) 0.1 M NaCl and b) 0.1 M Na₂SO₄ in the presence of different concentrations of DD.

3.7.4 Adsorption isotherms

Efforts were made to fit the values of θ and C_{inh} graphically, into different adsorption isotherms such as Langmuir, Temkin, Frumkin, Flory-Huggins isotherms, etc. The regression coefficients (R^2) obtained with Langmuir isotherm is close to unity. Figure 3.79 shows the Langmuir adsorption isotherms for the adsorption of DD on AZ31 alloy surface in 0.1 M NaCl and 0.1 M Na₂SO₄ at different temperatures.

The thermodynamic parameters for the adsorption of DD in 0.1 M NaCl and Na₂SO₄ solution are tabulated in Tables 3.133 and 3.134. The linear regression coefficient and slopes of the plots were close to 1 showing a slight deviation from the Langmuir isotherm. This would have been caused due to the mutual interaction of the adsorbed inhibitor molecules on the surface of the alloy (Masel 1996). The values obtained for ΔG_{ads}^0 are negative and in between -29.5 kJ mol⁻¹ to -36 kJ mol⁻¹, indicating that the adsorption is through both physisorption and chemisorption. The ΔH_{ads}^0 is in the range between -19.34 kJ mol⁻¹ to -91.77 kJ mol⁻¹ implying a predominantly physisorption process.

Fig. 3.79: Langmuir adsorption isotherms for the adsorption of DD on AZ31 magnesium alloy in a) NaCl medium and b) Na₂SO₄ medium.

3.7.5 SEM

Fig. 3.80 depicts the SEM image and EDX spectrum of AZ31 Mg alloy surface immersed in 0.1 M NaCl solution in the presence of 0.0002 M DD. Fig. 3.81 presents the SEM image and EDX spectrum of AZ31 Mg alloy surface

immersed in 0.1 M Na_2SO_4 solution in the presence of 0.0002 M DD. In the EDX spectra apart from the peaks of Mg, Al, Zn, and Cl, additional small peaks for carbon, oxygen, and nitrogen are observed, which indicate the presence of some organic moieties on the alloy surface, possibly the surface adsorbed DD molecules. It is also observed that the intensity of the Mg peak is reduced.

Fig. 3.80: SEM image and EDX spectrum of the AZ31 magnesium alloy surface immersed in 0.1 M NaCl in the presence of DD for 3 h at 30 °C.

Fig. 3.81: SEM image and EDX spectrum of the AZ31 magnesium alloy surface immersed in 0.1 M Na_2SO_4 in the presence of DD for 3 h at 30 °C.

3.7.6 XPS

Fig. 3.82 and Fig. 3.83 show the XPS survey spectra and individual spectrum corresponding to different elements present on the surface of the AZ31

alloy immersed in 0.1 M NaCl and 0.1 M Na₂SO₄ media for 3 h in the presence of 0.001 M DD at 30 °C.

Fig. 3.82: XPS survey spectra and individual spectrum of elements (Mg 1s, Al 2p, C 1s, O 1s and, N 1s) of AZ31 Mg alloy immersed in 0.1 M NaCl medium in the presence of 0.0002 M DD for 3 h at 30 °C.

Fig. 3.83: XPS survey spectra and individual spectrum of elements (Mg 1s, Al 2p, C 1s, O 1s and, N 1s) of AZ31 Mg alloy immersed in 0.1 M Na₂SO₄ medium in the presence of 0.0002 M DD for 3 h at 30 °C.

The high-resolution Mg 2s spectrum for magnesium alloys immersed in DD inhibitor has peaks assigned to Mg, MgO, and Mg(OH)₂.

The high-resolution Mg 2s spectrum for magnesium alloys immersed in DC inhibitor has peaks assigned to Mg, MgO, and Mg(OH)₂. The corrosion is retarded since the peak area of Mg is larger than Mg(OH)₂. For O 1s spectrum, the peak ~531.2 corresponds to MgO. The Al 2p spectra show a broad peak centered at 74.7 eV which indicates the co-existence of aluminum oxide or aluminum hydroxide. The C 1s spectra can be fitted to the presence of C-C/C-H groups at peak 284.8 eV. N 1s spectrum shows a peak at 399.2 eV, which shows the presence of C-N bond. The XPS results show that the inhibitor is on the surface.

3.7.7 DFT

The optimized structure for the inhibitor, DD, was obtained using DFT calculations at the B3LYP hybrid functional model with def-TZVP basis set and presented in Fig. 3.84. The calculated parameters are presented in Table 3.135.

The structure of the molecule is optimized and the negative value of the total energy (-2.943 KeV) indicates a thermodynamically stable molecule. E_{HOMO} value of -0.78 eV for the inhibitor DD, indicates the physical adsorption as the basis for the corrosion inhibition action. The low bandgap energy suggests a higher reactivity of the inhibitor molecules, leading to their ready adsorption on AZ31 alloy surface (H. A. Videla; M. F. L. de Mele; G. Brankevich 1988)(Williams et al. 2013)(Liu et al. 2018). The high value of the dipole moment implies a stronger interaction of DD molecules with the AZ31 alloy surface.

Fig. 3.84: Optimized structure and the frontier molecular orbital density distribution of the DD molecule.

3.7.8 Comparison of inhibitors efficiencies of the inhibitors

The inhibition efficiencies of the five inhibitors vary in the following order in both the media is $DD > DC > DO > DH > DB$. The surfactants are surface-active agents that exhibit a unique tendency to self-aggregate in solutions and at interfaces, above a definite threshold concentration. The higher inhibition has been observed in DD could be explained with the help of skeletal structure. DD could accumulate on a greater surface area of the alloy due to the presence of large alkyl chain attached to the amine group. The inhibition efficiency decreases with the decrease in the length of the alkyl chain. The inhibition efficiency of DB is least among all the studied inhibitors as it has a small alkyl chain to it compared to other inhibitors.

The examined anionic Gemini surfactants possess both a hydrophilic head and a long alkyl hydrophobic tail. The thermodynamic parameters evaluated in the present study hinted at the possible occurrence of both types of adsorption; physisorption and chemisorption during the interaction of carboxylates with AZ31 alloy surface. At the surface, there can be a strong donor-acceptor interactions might occur between the unshared electrons of the

anionic Gemini surfactants and the vacant d-orbitals of the magnesium. The diacetate end of the inhibitor molecules can be chemisorbed along with the secondary phases, most likely blocking the active cathodic reaction sites and hence impede the cathodic hydrogen evolution reaction. The electrostatic interactions are most likely between the anionic head of the surfactants and magnesium ions (Mg^{2+}) confined within the defects of the surface film developed over α -Mg matrix.

The low solubility products of magnesium salts of the surfactant inhibitors are easily exceeded due to the presence of a surplus of dissolved Mg^{2+} ions, and hence the physisorbed diacetates preferentially precipitate as magnesium salts within defects of the surface film over the α -Mg matrix. The precipitates fill up the pores and appreciably rectify the defects of the surface film. The modified surface film, owing to the presence of precipitated film might also acquire hydrophobicity to some extent, which is advantageous given the tendency of the hydrophobic film to repel the aqueous electrolyte. The deviation from ideal Langmuir behavior observed for all the inhibitors hinted at the existence of intermolecular forces which in all likelihood are van der Waals interactions existing between the long alkyl chains of adsorbed inhibitor molecules. Such mutual interactions might further contribute towards the densification of the film. To sum up, the inhibitors are instrumental in the formation of a compact modified surface film over α -Mg matrix, which subsequently impedes the anodic reaction of magnesium dissolution through an enhanced barrier effect against electrolyte ingress. This mechanism suggesting the compaction of the surface film on the addition of inhibitors is corroborated by some results of the study, like the Bode phase angle plots and the impedance parameters such as film resistance, film capacitance whose variations collectively pointed out the augmentation of the barrier effect, the resistance and the thickness of the surface film in the presence of the inhibitors.

To be able to explain the inhibition performance of the investigated anionic Gemini surfactants, we scanned the selectivity descriptors and molecular reactivity for these inhibitors. In this study, some quantum

calculations were carried out to explain the mode of adsorption of the five studied compounds. The optimized geometry of the anionic Gemini surfactants and their HOMO and LUMO distributions were shown in each sections. According to the frontier molecular orbital theory, E_{HOMO} is connected with the ability of the molecule to donate the electron to the vacancy d-orbital of the alloy surface. On the other hand, E_{LUMO} is related to the electron-accepting ability of the i.e. lower its value higher would be its electron-accepting tendency from the filled metal orbitals. Based on EIS and potentiodynamic polarization measurements, the order of inhibition efficiency for the investigated surfactants is $\text{DD} > \text{DC} > \text{DO} > \text{DH} > \text{DB}$. It is known that E_{HOMO} negative sign has been explained by some authors to be an indication of physisorption rather than chemisorption. As the energy gap values decrease, the reactivity of the molecules increases, leading to an increase in adsorption of inhibitor molecules on the AZ31 alloy surface and consequently an increase in the inhibition efficiency. The dipole moment (μ) is another index that is predominantly utilized for the prediction of the direction of the inhibition of corrosion process. It is related to the distribution of electrons in a molecule and is the measure of polarity in a bond. The compounds with high dipole moment tend to form strong dipole-dipole interactions, intermolecular forces with the AZ31 alloy surface, leading to resulting in strong adsorption on the metal surface and hence resulting in better efficiencies. The theoretical data obtained for the inhibitors are in support of the observed trend.

3.7.9 SUMMARY

Anionic Gemini surfactant, DD, was synthesized and used as a corrosion inhibitor on AZ31 Mg alloy in different concentrations of NaCl solution and Na_2SO_4 solution. The surfactant DD acted as a mixed type of inhibitor and the inhibitor efficiency increased with the increase in the concentration of DD and decreased with the rise in temperature and the increase in the concentration of NaCl and Na_2SO_4 media. The surfactant was adsorbed predominantly through physisorption and obeyed Langmuir adsorption isotherm. The quantum chemical calculation supported the experimental observation.

CHAPTER-4
SUMMARY AND CONCLUSIONS

CHAPTER 4

SUMMARY AND CONCLUSION

4.1 SUMMARY

The corrosion behavior of AZ31 Mg alloy in sodium chloride and sodium sulfate media was confirmed. The complete investigation was an electrochemical impedance technique for understanding the overall phenomenon. The environmental factors like ionic concentration of the medium, solution temperature, and pH were varied to grasp the influence of each of these factors on the anodic dissolution of AZ31 Mg alloy. Moreover, studying the AZ31 alloy corrosion in different temperatures was helpful for the evaluation of the activation parameters. The continuance of a partly protective corrosion product surface film, having a remarkable impact on the corrosion behavior of AZ31 alloy was declared from the results of electrochemical and surface analyses studies.

Five long-chain alkyl diacetates; DB, DH, DO, DC, and DD were studied for their efficacy to resist corrosion of magnesium alloy AZ31 Mg alloy in sodium chloride and sodium sulfate solution. The inhibition tests were conducted at various medium concentrations and solution temperatures to find out the effect of ionic concentration of the media and that of temperature on the inhibition efficiency of the diacetates. At every varying inhibitor concentration in a range to establish the optimum concentration for inhibition. The examination involving different inhibitors appears to produce results that helped to comprehend the impact of molecular structure of the inhibitor on the inhibition efficiency. The activation and thermodynamic parameters and DFT (Theoretical) were evaluated to support a complete apprehension of alloy dissolution and interfacial adsorption, respectively. The trends in the variation of all the electrochemical, activation, and thermodynamic parameters reported in the study have been accounted concisely.

Anodic dissolution of magnesium and cathodic hydrogen evolution is inhibited by the addition of anionic Gemini surfactants namely DB, DH, DO,

DC, and DD in NaCl and Na₂SO₄ solution. Adsorption of surfactants in the corrosion product is set to form a hydrophobic outer corrosion layer. The efficiency of the inhibitors was demonstrated by potentiodynamic polarization and electrochemical impedance spectroscopy and supported by surface analysis and theoretical calculations.

Potentiodynamic polarization plots indicate that all the five inhibitors used show a mixed-type corrosion inhibitor suppressing both anodic and cathodic reactions. The adsorption film formed after the introduction of the inhibitor is supported by SEM-EDX and XPS. Both adsorption and chemical reaction between the inhibitor and AZ31 Mg alloys result in the formation of a film on the alloy surface. It is in agreement with the XPS and theoretical results. A significant increase in the inhibition efficiency is seen when inhibitors concentration increases to an optimum concentration level, beyond which the increase in the inhibition efficiency is negligible. As the temperature of the system increases, there is a decrease in the inhibition efficiency of surfactant inhibitors. In economic concentration, DD showed the highest inhibition efficiency followed by DC, DO, DH and DB. The difference in aliphatic chains of inhibitors attributes to the change in its inhibition efficiency as it controls over the solubility product of magnesium salts.

The electrochemical results along with SEM-EDX and XPS analysis were taken into consideration for suggesting a credible mechanism for inhibition of AZ31 alloy corrosion by alkyl chains. The chemisorption of the diacetates at the cathodic phases was surmised to block the active reaction sites on the alloy surface, thereby resulting in cathodic inhibition. The anodic inhibition was considered to ensue as a consequence of compaction and thickening of the porous surface film at anodic phases through precipitation of magnesium diacetates. Such densification was supposed to add the barrier effect of the surface film against the electrolyte ingress. The slight deviation from ideal Langmuir behavior was observed and was attributed to intermolecular forces like van der Waals interactions existing between the long alkyl chains of the adsorbed diacetate molecules. Such mutual interactions were believed to further

contribute towards the densification of the film. The theoretical studies (DFT) were performed to support the experimental studies which significantly showed the efficiency of diacetate inhibitors.

4.2 CONCLUSIONS

From the above results and discussion, the main conclusions can be summarized in the following points:

1. A higher ionic concentration, higher temperature, and acidic pH bring about destabilization and dissolution of the corrosion product surface film; hence accelerating the rate of AZ31 alloy corrosion.
2. The corrosion kinetics follows Arrhenius law in both the media.
3. The corrosion behavior of AZ31 Mg alloy in sodium chloride and sodium sulfate solutions is strongly influenced by the medium pH. The corrosion rate decreases with the increase in medium pH. The relatively high corrosion resistance in basic solutions is attributed to the formation of the stable $\text{Mg}(\text{OH})_2$ barrier film on the alloy surface.
4. The inhibitors, DB, DH, DO, DC, and DD act as mixed-type inhibitors. The increase in inhibition efficiency with the increase in the inhibitor concentration is maximum up to an optimum concentration above which the increase in inhibition efficiency is negligible.
5. The increase in temperature decreases the inhibition efficiency of the inhibitors.
6. The adsorption of the inhibitor molecules on the alloy surface is principally physisorption and complies with the Langmuir adsorption isotherm.
7. The surfactant DD exhibits the highest inhibition efficiency followed by DC, DO, DH, and DB.

4.3 SCOPE FOR FUTURE WORK

1. The corrosion behavior and inhibition of different heat-treated AZ31 Mg alloys can be explored.
2. To carry out electrochemical investigations on AZ31 Mg alloy in media containing living cells and proteins in order to use it in medical implants.
3. The electrochemical studies can be carried out by varying the immersion time, corrosive medium, and deoxygenated environment to understand the efficiency of the surface film during long exposure periods.
4. The negative difference effect (NDE) can be experimentally verified by comparing the results of the present electrochemical study with those derived from weight loss or hydrogen evolution measurements.

CURRICULUM VITAE

GURURAJ ACHARYA M

PRESENT ADDRESS

Department of Chemistry
National Institute of Technology Karnataka
Surathkal, Mangalore-575025
Karnataka, India

PERMANENT ADDRESS

#8-11, Eshavasyam, Mundkur
village, Udupi-576121
Karnataka, India

CONTACT DETAILS

Email: mgj1992@gmail.com

Mobile: +918056289150

EDUCATION

Doctor of Philosophy (Ph.D.) Chemistry, National Institute of Technology- Karnataka, (NITK) Surathkal, India	July 2016 - present
Masters of Science (M.Sc.) General Chemistry, Madras University, Tamil Nadu, India	2015 First Class with Distinction (7.57 CGPA)
Bachelor of Science (B.Sc) Physics, Chemistry, Mathematics (PCM) Karnataka University Dharwad, Karnataka, India	2013 First Class with Distinction (7.48 CGPA)
Higher Secondary (10+2) Department of State Board, Tamil Nadu, India	2010 First Class with Distinction (83 %)

RESEARCH EXPERIENCE

07/2015 - 04/2016 (Supervisor: Dr. Geetha Bhaskar, & Dr. Suguna)	CLRI, Chennai	Research Project Assistant	Flame retardant substances
11/2012 - 01/2013 (Supervisor: Dr. Srinivasan)	SGS, Chennai	Summer Intern	Quality Control
07/2016- ongoing (Supervisor: Prof. A. N. Shetty)	National Institute of Technology-Karnataka, (NITK)- Surathkal	Doctoral Student	Corrosion Science

PERSONAL INFORMATION

Sex: Male
Nationality: Indian
Languages: English, Tamil, Hindi, Kannada, French (Elementary)
